CANNON-THURSTON MAPS FOR SURFACE GROUPS: AN EXPOSITION OF AMALGAMATION GEOMETRY AND SPLIT GEOMETRY

MAHAN MJ

Abstract. This is an expository paper, aimed at giving a leisurely account of some model geometries associated to surface Kleinian groups. We describe the notion of manifolds of amalgamation geometry and its generalization, split geometry. We show that the limit set of any surface group of split geometry is locally connected, by constructing a natural Cannon-Thurston map.

An earlier version of this paper [Mj05a] had been written as the first of a two-part paper proving the existence of Cannon-Thurston Maps for surface Kleinian groups.
1. Introduction

In [Mj06] we prove the existence of Cannon-Thurston maps for arbitrary surface Kleinian groups without accidental parabolics. The proof proceeds by constructing a coarse model geometry, called split geometry, satisfied by all associated hyperbolic 3-manifolds. In this paper we give an expository account of the model geometries that go into [Mj06].

1.1. Questions, Conjectures and Statement of Results. In Section 6 of [CT85], Cannon and Thurston raise the following problem:

**Question 1.1.** Suppose a closed surface group \( \pi_1(S) \) acts freely and properly discontinuously on \( \mathbb{H}^3 \) by isometries. Does the inclusion \( \tilde{i} : \tilde{S} \to \mathbb{H}^3 \) extend continuously to the boundary?

The authors of [CT85] point out that for a simply degenerate group, this is equivalent to asking if the limit set is locally connected.

In [McM01], McMullen makes the following more general conjecture:

**Conjecture 1.2.** For any hyperbolic 3-manifold \( N \) with finitely generated fundamental group, there exists a continuous, \( \pi_1(N) \)-equivariant map

\[
F : \partial \pi_1(N) \to \Lambda \subset S^2_{\infty}
\]

where the boundary \( \partial \pi_1(N) \) is constructed by scaling the metric on the Cayley graph of \( \pi_1(N) \) by the conformal factor of \( d(e,x)^{-2} \), then taking the metric completion. (cf. Floyd [Flo80])

The author raised the following question in his thesis [Mit97] (see also [Bes04]):

**Question 1.3.** Let \( G \) be a hyperbolic group in the sense of Gromov acting freely and properly discontinuously by isometries on a hyperbolic metric space \( X \). Does the inclusion of the Cayley graph \( i : \Gamma_G \to X \) extend continuously to the (Gromov) compactifications?

A similar question may be asked for relatively hyperbolic groups (in the sense of Gromov [Gro85] and Farb [Far98]).

The question for relatively hyperbolic groups unifies all the above questions and conjectures.

In this paper we describe a model geometry we call amalgamation geometry which is, in a way, a considerable generalization of the notion of \( i \)-bounded geometry introduced in [Mj05b]. We then further generalize it by weakening the hypothesis to the notion of split geometry. For ease of exposition we shall restrict ourselves to surfaces without punctures (parabolics). The main Theorem of this paper is the following.
Theorem 8.3: Let $\rho : \pi_1(S) \to PSL_2(C)$ be a faithful representation of a surface group with or without punctures, and without accidental parabolics. Let $M = H^3/\rho(\pi_1(S))$ be of split geometry. Let $i$ be an embedding of $S$ in $M$ that induces a homotopy equivalence. Then the embedding $\bar{i} : \bar{S} \to \bar{M} = H^3$ extends continuously to a map $\hat{i} : D^2 \to D^3$. Further, the limit set of $\rho(\pi_1(S))$ is locally connected.

1.2. History. In [Abi76], Abikoff (1976) claimed that limit sets of simply degenerate surface Kleinian groups were never locally connected. Thurston and Kerckhoff found a flaw in his proof in about 1980.

The first major positive result was proved by Cannon and Thurston [CT85] [CT07] for hyperbolic 3-manifolds fibering over the circle with fiber a closed surface group.

This was generalized by Minsky who proved the Cannon-Thurston result for bounded geometry Kleinian closed surface groups [Min94].

An alternate approach was given by the author in [Mit98b] proving the Cannon-Thurston result for hyperbolic 3-manifolds of bounded geometry without parabolics and with freely indecomposable fundamental group. A different approach based on Minsky’s work was given by Klarreich [Kla99]. In [Mit98a] we gave some further extensions to the domain of Gromov-hyperbolic groups (see also [MP10]).

Bowditch [Bow07] [Bow02] proved the Cannon-Thurston result for punctured surface Kleinian groups of bounded geometry. In [Mj09] we extended Bowditch’s results to 3 manifolds of bounded geometry whose cores are incompressible away from cusps (see also [Mj10a]).

McMullen [McM01] proved the Cannon-Thurston result for punctured torus groups, using Minsky’s model for these groups [Min99]. In [Mj05b] we identified a large-scale coarse geometric structure involved in the Minsky model for punctured torus groups (and called it i-bounded geometry). We gave a proof for models of i-bounded geometry.

In this paper, we define amalgamation geometry and prove the Cannon-Thurston result for models of amalgamation geometry. We then weaken this assumption to what we call split geometry and prove the Cannon-Thurston property for such geometries. In [Mj06] we show that the Minsky model for general simply or totally degenerate surface groups [Min02] [BCM04] gives rise to a model of split geometry. This shows that all surface groups have the Cannon-Thurston property and hence have locally connected limit sets. In [Mj10b] we extend the results of [Mj06] to all finitely generated Kleinian groups. In [DM10b], [Mj07] and [DM10a] we describe point-images of Cannon-Thurston maps.

2. Preliminaries and Amalgamation Geometry

2.1. Hyperbolic Metric Spaces. We start off with some preliminaries about hyperbolic metric spaces in the sense of Gromov [Gro85]. For details, see [CDA90], [GdlH90]. Let $(X, d)$ be a hyperbolic metric space. The Gromov boundary of $X$, denoted by $\partial X$, is the collection of equivalence classes of geodesic rays $r : [0, \infty) \to \Gamma$ with $r(0) = x_0$ for some fixed $x_0 \in X$, where rays $r_1$ and $r_2$ are equivalent if $\sup \{d(r_1(t), r_2(t))\} < \infty$. Let $\bar{X} = X \cup \partial X$ denote the natural compactification of $X$ topologized the usual way (cf. [GdlH90] pg. 124).

**Definition 2.1.** A subset $Z$ of $X$ is said to be $k$-quasiconvex if any geodesic joining points of $Z$ lies in a $k$-neighborhood of $Z$. A subset $Z$ is quasiconvex if it
is $k$-quasiconvex for some $k$. (For simply connected real hyperbolic manifolds this is equivalent to saying that the convex hull of the set $Z$ lies in a bounded neighborhood of $Z$. We shall have occasion to use this alternate characterization.) A map $f$ from one metric space $(Y,d_Y)$ into another metric space $(Z,d_Z)$ is said to be a $(K,\epsilon)$-quasi-isometric embedding if
\[
\frac{1}{K}(d_Y(y_1,y_2)) - \epsilon \leq d_Z(f(y_1), f(y_2)) \leq Kd_Y(y_1,y_2) + \epsilon
\]
If $f$ is a quasi-isometric embedding, and every point of $Z$ lies at a uniformly bounded distance from some $f(y)$ then $f$ is said to be a **quasi-isometry**. A $(K,\epsilon)$-quasi-isometric embedding that is a quasi-isometry will be called a $(K,\epsilon)$-quasi-isometry.

A $(K,\epsilon)$-quasigeodesic is a $(K,\epsilon)$-quasi-isometric embedding of a closed interval in $\mathbb{R}$. A $(K,K)$-quasigeodesic will also be called a $K$-quasigeodesic.

Let $(X,d_X)$ be a hyperbolic metric space and $Y$ be a subspace that is hyperbolic with the inherited path metric $d_Y$. By adjoining the Gromov boundaries $\partial X$ and $\partial Y$ to $X$ and $Y$, one obtains their compactifications $\hat{X}$ and $\hat{Y}$ respectively.

Let $i: Y \to X$ denote inclusion.

**Definition 2.2.** Let $X$ and $Y$ be hyperbolic metric spaces and $i: Y \to X$ be an embedding. A Cannon-Thurston map $i$ from $\hat{Y}$ to $\hat{X}$ is a continuous extension of $i$.

The following lemma (Lemma 2.1 of [Mit98a]) says that a Cannon-Thurston map exists if for all $M > 0$ and $y \in Y$, there exists $N > 0$ such that if $\lambda$ lies outside an $N$-ball around $y$ in $Y$ then any geodesic in $X$ joining the end-points of $\lambda$ lies outside the $M$ ball around $i(y)$ in $X$. For convenience of use later on, we state this somewhat differently.

**Lemma 2.3.** A Cannon-Thurston map from $\hat{Y}$ to $\hat{X}$ exists if the following condition is satisfied:

Given $y_0 \in Y$, there exists a non-negative function $M(N)$, such that $M(N) \to \infty$ as $N \to \infty$ and for all geodesic segments $\lambda$ lying outside an $N$-ball around $y_0 \in Y$ any geodesic segment in $\Gamma_G$ joining the end-points of $i(\lambda)$ lies outside the $M(N)$-ball around $i(y_0) \in X$.

The above result can be interpreted as saying that a Cannon-Thurston map exists if the space of geodesic segments in $Y$ embeds properly in the space of geodesic segments in $X$.

2.2. **Amalgamation Geometry.** We start with a hyperbolic surface $S$ without punctures. The hyperbolic structure is arbitrary, but it is important that a choice be made.

**The Amalgamated Building Block.**

For the construction of an amalgamated block $B$, $I$ will denote the closed interval $[0,3]$. We will describe a geometry on $S \times I$. $B$ has a geometric core $K$ with bounded geometry boundary and a preferred geodesic $\gamma(=\gamma_B)$ of bounded length.

There will exist $\epsilon_0,\epsilon_1, D$ (independent of the block $B$) such that the following hold:

1) $B$ is identified with $S \times I$
2) $B$ has a geometric core $K$ identified with $S \times [1,2]$. ($K$, in its intrinsic path metric, may be thought of, for convenience, as a convex hyperbolic manifold with boundary consisting of pleated surfaces. But we will have occasion to use geometries
that are only quasi-isometric to such geometries when lifted to universal covers. As of now, we do not impose any further restriction on the geometry of \(K\).

3) \(\gamma\) is homotopic to a simple closed curve on \(S \times \{i\}\) for any \(i \in I\).

4) \(\gamma\) is small, i.e. the length of \(\gamma\) is bounded above by \(\epsilon_0\).

5) The intrinsic metric on \(S \times i\) (for \(i = 1, 2\)) has bounded geometry, i.e. any closed geodesic on \(S \times \{i\}\) has length bounded below by \(\epsilon_1\). Further, the diameter of \(S \times \{i\}\) is bounded above by \(D\). (The latter restriction would have followed naturally had we assumed that the curvature of \(S \times \{i\}\) is hyperbolic or at least pinched negative.)

6) There exists a regular neighborhood \(N_k(\gamma) \subset K\) of \(\gamma\) which is homeomorphic to a solid torus, such that \(N_k(\gamma) \cap S \times \{i\}\) is homeomorphic to an open annulus for \(i = 1, 2\). We shall have occasion to denote \(N_k(\gamma)\) by \(T_\gamma\) and call it the Margulis tube corresponding to \(\gamma\).

7) \(S \times [0, 1]\) and \(S \times [1, 2]\) are given the product structures corresponding to the bounded geometry structures on \(S \times \{i\}\), for \(i = 1, 2\) respectively.

We next describe the geometry of the geometric core \(K\). \(K - T_\gamma\) has one or two components according as \(\gamma\) does not or does separate \(S\). These components shall be called amalgamation components of \(K\). Let \(K_1\) denote such an amalgamation component. Then a lift \(\widetilde{K}_1\) of \(K_1\) to \(\tilde{K}\) is bounded by lifts \(\tilde{T}_\gamma\) of \(T_\gamma\). The union of such a lift \(\widetilde{K}_1\) along with the lifts \(\tilde{T}_\gamma\) that bound it will be called an amalgamation component of \(\tilde{K}\).

Note that two amalgamation components of \(\tilde{K}\), if they intersect, shall do so along a lift \(\tilde{T}_\gamma\) of \(T_\gamma\). In this case, they shall be referred to as adjacent amalgamation components.

In addition to the above structure of \(B\), we require in addition that there exists \(C > 0\) (independent of \(B\)) such that

- Each amalgamation component of \(\tilde{K}\) is \(C\)-quasiconvex in the intrinsic metric on \(\tilde{K}\).

Note 1: Quasiconvexity of an amalgamation component follows from the fact that any geometric subgroup of infinite index in a surface group is quasiconvex in the latter. The restriction above is therefore to ensure uniform quasiconvexity. We shall strengthen this restriction further when we describe the geometry of \(\tilde{M}\), where \(M\) is a 3-manifold built up of blocks of amalgamation geometry and those of bounded geometry by gluing them end to end. We shall require that each amalgamation component is uniformly quasiconvex in \(\tilde{M}\) rather than just in \(\tilde{K}\).

Note 2: So far, the restrictions on \(K\) are quite mild. There are really two restrictions. One is the existence of a bounded length simple closed geodesic whose regular neighborhood intersects the bounding surfaces of \(K\) in annuli. The second restriction is that the two boundary surfaces of \(K\) have bounded geometry.

The copy of \(S \times I\) thus obtained, with the restrictions above, will be called a building block of amalgamated geometry or an amalgamation geometry building block, or simply an amalgamation block.

Thick Block

Fix constants \(D, \epsilon\) and let \(\mu = [p, q]\) be an \(\epsilon\)-thick Teichmuller geodesic of length less than \(D\). \(\mu\) is \(\epsilon\)-thick means that for any \(x \in \mu\) and any closed geodesic \(\eta\) in the hyperbolic surface \(S_x\) over \(x\), the length of \(\eta\) is greater than \(\epsilon\). Now let \(B\) denote
the universal curve over \( \mu \) reparametrized such that the length of \( \mu \) is covered in unit time. Thus \( B = S \times [0, 1] \) topologically.

\( B \) is given the path metric and is called a thick building block.

Note that after acting by an element of the mapping class group, we might as well assume that \( \mu \) lies in some given compact region of Teichmüller space. This is because the marking on \( S \times \{0\} \) is not important, but rather its position relative to \( S \times \{1\} \). Further, since we shall be constructing models only up to quasi-isometry, we might as well assume that \( S \times \{0\} \) and \( S \times \{1\} \) lie in the orbit under the mapping class group of some fixed base surface. Hence \( \mu \) can be further simplified to be a Teichmüller geodesic joining a pair \((p, q)\) amongst a finite set of points in the orbit of a fixed hyperbolic surface \( S \).

**The Model Manifold**

Note that the boundary of an amalgamation block \( B_i \) consists of \( S \times \{0, 3\} \) and the intrinsic path metric on each such \( S \times \{0\} \) or \( S \times \{3\} \) is of bounded geometry. Also, the boundary of a thick block \( B \) consists of \( S \times \{0, 1\} \), where \( S_0, S_1 \) lie in some given bounded region of Teichmüller space. The intrinsic path metrics on each such \( S \times \{0\} \) or \( S \times \{1\} \) is the path metric on \( S \).

The model manifold of amalgamation geometry is obtained from \( S \times J \) (where \( J \) is a sub-interval of \( \mathbb{R} \), which may be semi-infinite or bi-infinite. In the former case, we choose the usual normalization \( J = [0, \infty) \) ) by first choosing a sequence of blocks \( B_i \) (thick or amalgamated) and corresponding intervals \( I_i = [0, 1] \) or \( [0, 3] \) according as \( B_i \) is thick or amalgamated. The metric on \( S \times I_i \) is then declared to be that on the building block \( B_i \). Implicitly, we are requiring that the surfaces along which gluing occurs have the same metric. Thus we have,

**Definition 2.4.** A manifold \( M \) homeomorphic to \( S \times J \), where \( J = [0, \infty) \) or \( J = (-\infty, \infty) \), is said to be a model of amalgamation geometry if

1) there is a fiber preserving homeomorphism from \( M \) to \( \tilde{S} \times J \) that lifts to a quasi-isometry of universal covers

2) there exists a sequence \( I_i \) of intervals (with disjoint interiors) and blocks \( B_i \) where the metric on \( S \times I_i \) is the same as that on some building block \( B_i \)

3) \( \bigcup I_i = J \)

4) There exists \( C > 0 \) such that for all amalgamated blocks \( B \) and geometric cores \( K \subset B \), all amalgamation components of \( \tilde{K} \) are \( C \)-quasiconvex in \( \tilde{M} \)

The last restriction (4) above is a global restriction on the geometry of amalgamation components, not just a local one (i.e. quasiconvexity in \( \tilde{M} \) rather than \( \tilde{B} \) is required.)

The figure below illustrates schematically what the model looks like. Filled squares correspond to solid tori along which amalgamation occurs. The adjoining piece(s) denote amalgamation blocks of \( K \). The blocks which have no filled squares are the thick blocks and those with filled squares are the amalgamated blocks.
Definition 2.5. A manifold $M$ homeomorphic to $S \times J$, where $J = [0, \infty)$ or $J = (-\infty, \infty)$, is said to have **amalgamated geometry** if there exists $K, \epsilon > 0$ and a model manifold $M_1$ of amalgamation geometry such that

1) there exists a homeomorphism $\phi$ from $M$ to $M_1$. This induces from the block decomposition of $M_1$ a block decomposition of $M$.

2) We require in addition that the induced homeomorphism $\bar{\phi}$ between universal covers of blocks is a $(K, \epsilon)$ quasi-isometry.

We shall usually suppress the homeomorphism $\phi$ and take $M$ itself to be a model manifold of amalgamation geometry.

**Note:** We shall later have occasion to introduce a different model, called the graph model.

3. Relative Hyperbolicity

In this section, we shall recall first certain notions of relative hyperbolicity due to Farb [Far98], Klarreich [Kla99] and the author [Mj05b]. Using these, we shall derive certain Lemmas that will be useful in studying the geometry of the universal covers of building blocks.

3.1. Electric Geometry. We start with a surface $S$ (assumed hyperbolic for the time being) of $(K, \epsilon)$ bounded geometry, i.e. $S$ has diameter bounded by $K$ and injectivity radius bounded below by $\epsilon$. Let $\sigma$ be a simple closed geodesic on $S$. Replace $\sigma$ by a copy of $\sigma \times [0, 1]$, by cutting open along $\sigma$ and gluing in a copy of $\sigma \times [0, 1] = A_\sigma$. (This is like ‘grafting’ but we shall not have much use for this similarity in this paper.) Let $S_G$ denote the grafted surface. $S_G - A_\sigma$ has one or two components according as $\sigma$ does not or does separate $S$. Call these **amalgamation component(s)** of $S$ We shall denote amalgamation components as $S_A$. We construct a pseudometric on $S_G$, by declaring the metric on each amalgamation component to be zero and to be the product metric on $A_\sigma$. Thus we define:

- the length of any path that lies in the interior of an amalgamation component to be zero
- the length of any path that lies in $A_\sigma$ to be its (Euclidean) length in the path metric on $A_\sigma$
- the length of any other path to be the sum of lengths of pieces of the above two kinds.
This allows us to define distances by taking the infimum of lengths of paths joining pairs of points and gives us a path pseudometric, which we call the electric metric on $S_G$. The electric metric also allows us to define geodesics. Let us call $S_G$ equipped with the above pseudometric $(S_Gel, d_{Gel})$ (to be distinguished from a ‘dual’ construction of an electric metric $S_{el}$ used in [Mj05b], where the geodesic $\sigma$, rather than its complementary component(s) is electrocuted.)

Important Note: We may and shall regard $S$ as a graph of groups with vertex group(s) the subgroup(s) corresponding to amalgamation component(s) and edge group $Z$, the fundamental group of $A_\sigma$. Then $\tilde{S}$ equipped with the lift of the above pseudometric is quasi-isometric to the tree corresponding to the splitting on which $\pi_1(S)$ acts.

We shall be interested in the universal cover $\tilde{S}_{Gel}$ of $S_{Gel}$. Paths in $S_{Gel}$ and $\tilde{S}_{Gel}$ will be called electric paths (following Farb [Far98]). Geodesics and quasigeodesics in the electric metric will be called electric geodesics and electric quasigeodesics respectively.

Definition 3.1. A path $\gamma : I \to Y$ in a path metric space $Y$ is a $K$-quasigeodesic if we have

$$L(\beta) \leq KL(A) + K$$

for any subsegment $\beta = \gamma|[a,b]$ and any rectifiable path $A : [a,b] \to Y$ with the same endpoints.

$\gamma$ is said to be an electric $K,\epsilon$-quasigeodesic in $\tilde{S}_{Gel}$ without backtracking if $\gamma$ is an electric $K$-quasigeodesic in $\tilde{S}_{Gel}$ and $\gamma$ does not return to any lift $S_A \subset \tilde{S}_{Gel}$ (of an amalgamation component $S_A \subset S$) after leaving it.

We collect together certain facts about the electric metric that Farb proves in [Far98]. $N_R(Z)$ will denote the $R$-neighborhood about the subset $Z$ in the hyperbolic metric. $N^e_R(Z)$ will denote the $R$-neighborhood about the subset $Z$ in the electric metric.

Lemma 3.2. (Lemma 4.5 and Proposition 4.6 of [Far98])

1. Electric quasi-geodesics electrically track hyperbolic geodesics: Given $P > 0$, there exists $K > 0$ with the following property: For some $S_{Gel}$, let $\beta$ be any electric $P$-quasigeodesic without backtracking from $x$ to $y$, and let $\gamma$ be the hyperbolic geodesic from $x$ to $y$. Then $\beta \subset N^e_K(\gamma)$.

2. Hyperbolicity: There exists $\delta$ such that each $\tilde{S}_{Gel}$ is $\delta$-hyperbolic, independent of the curve $\sigma$ whose lifts are electrocuted.

Note: As pointed out before, $S_{Gel}$ is quasi-isometric to a tree and is therefore hyperbolic. The above assertion holds in far greater generality than stated. We discuss this below.

We consider a hyperbolic metric space $X$ and a collection $\mathcal{H}$ of (uniformly) $C$-quasiconvex uniformly separated subsets, i.e. there exists $D > 0$ such that for $H_1, H_2 \in \mathcal{H}$, $d_X(H_1, H_2) \geq D$. In this situation $X$ is hyperbolic relative to the collection $\mathcal{H}$. The result in this form is due to Klarreich [Kla99]. We give the general version of Farb’s theorem below and refer to [Far98] and Klarreich [Kla99] for proofs.
**Lemma 3.3.** (See Lemma 4.5 and Proposition 4.6 of [Far98] and Theorem 5.3 of Klarreich [Kla99]) Given $\delta, C, D$ there exists $\Delta$ such that if $X$ is a $\delta$-hyperbolic metric space with a collection $\mathcal{H}$ of $C$-quasiconvex $D$-separated sets, then,

1. Electric quasi-geodesics electrically track hyperbolic geodesics: Given $P > 0$, there exists $K > 0$ with the following property: Let $\beta$ be any electric $P$-quasigeodesic from $x$ to $y$, and let $\gamma$ be the hyperbolic geodesic from $x$ to $y$. Then $\beta \subset N_K(\gamma)$.

2. $\gamma$ lies in a hyperbolic $K$-neighborhood of $N_0(\beta)$, where $N_0(\beta)$ denotes the zero neighborhood of $\beta$ in the electric metric.

3. Hyperbolicity: $X$ is $\Delta$-hyperbolic.

A special kind of geodesic without backtracking will be necessary for universal covers $\widetilde{S_Gel}$ of surfaces with some electric metric. Let $\sigma, A_{\sigma}$ be as before.

Let $\lambda_{\text{e}}$ be an electric geodesic in some $(\widetilde{S_Gel}, d_{\text{Gel}})$. Then, each segment of $\lambda_{\text{e}}$ between two lifts $\widetilde{A}_{\sigma}$ of $A_{\sigma}$ (i.e. lying inside a lift of an amalgamation component) is required to be perpendicular to the bounding geodesics. We shall refer to these segments of $\lambda_{\text{e}}$ as amalgamation segments because they lie inside lifts of the amalgamation components.

Let $a, b$ be the points at which $\lambda_{\text{e}}$ enters and leaves a lift $\widetilde{A}_{\sigma}$ of $A_{\sigma}$. If $a, b$ lie on the same side, i.e. on a lift of either $\sigma \times \{0\}$ or $\sigma \times \{1\}$, then we join $a, b$ by the geodesic joining them. If they lie on opposite sides of $\widetilde{A}_{\sigma}$, then assume, for convenience, that $a$ lies on a lift of $\sigma \times \{0\}$ and $b$ lies on a lift of $\sigma \times \{1\}$. Then we join $a$ to $b$ by a union of 2 geodesic segments $[a, c]$ and $[d, b]$ lying along $\widetilde{\sigma} \times \{0\}$ and $\widetilde{\sigma} \times \{1\}$ respectively (for some lift $\widetilde{A}_{\sigma}$), along with a ‘horizontal’ segment $[c, d]$, where $[c, d] \subset \widetilde{A}_{\sigma}$ projects to a segment of the form $\{x\} \times [0, 1] \subset \sigma \times [0, 1]$. We further require that the sum of the lengths $d(a, c)$ and $d(d, b)$ is the minimum possible. The union of the three segments $[a, c], [c, d], [d, b]$ shall be denoted by $[a, b]_{\text{int}}$ and shall be referred to as an interpolating segment. See figure below.

![Figure 2: Interpolating segment](attachment:image.png)

The union of the amalgamation segments along with the interpolating segments gives rise to a preferred representative of a quasigeodesic without backtracking joining the end-points of $\lambda_{\text{Gel}}$. Such a representative of the class of $\lambda_{\text{Gel}}$ shall be called the canonical representative of $\lambda_{\text{Gel}}$. Further, the underlying set of the canonical representative in the hyperbolic metric shall be called the electro-ambient
representative $\lambda_q$ of $\lambda$. Since $\lambda$ turns out to be a hyperbolic quasigeodesic (Lemma 3.5 below), we shall also call it an **electro-ambient quasigeodesic**. See Figure 3 below:

![Figure 3: Electro-ambient quasigeodesic](image)

**Remark:** We note first that if we collapse each lift of $A_\sigma$ along the $I(= [0, 1])$-fibers, (and thus obtain a geodesic that is a lift of $\sigma$), then $\lambda_{Gel}$ becomes an electric geodesic $\lambda_{el}$ in the universal cover $\tilde{\mathcal{S}}_{el}$ of $\mathcal{S}_{el}$. Here $\mathcal{S}_{el}$ denotes the space obtained by electrocuting the geodesic $\sigma$ (See Section 3.1 of [Mj05b]).

Let $\tilde{c} : \tilde{\mathcal{S}}_G \to \tilde{\mathcal{S}}$ be the map that collapses $I$-fibers, i.e. it maps the annulus $A_\sigma = \sigma \times I$ to the geodesic $\sigma$ by taking $(x, t)$ to $x$. The lift $\tilde{\sigma} : \tilde{\mathcal{S}}_G \to \tilde{\mathcal{S}}$ collapses each lift of $A_\sigma$ along the $I(= [0, 1])$-fibers to a geodesic that is a lift of $\sigma$). Also it takes $\lambda_{Gel}$ to an electric geodesic $\lambda_{el}$ in the universal cover $\tilde{\mathcal{S}}_{el}$ of $\mathcal{S}_{el}$ (that $\lambda_{el}$ is an electric geodesic in $\tilde{\mathcal{S}}_{el}$ follows easily, say from normal forms). These were precisely the electro-ambient quasigeodesics in the space $\tilde{\mathcal{S}}, l$ (See Section 3.1 of [Mj05b] for definitions).

**Remark:** The electro-ambient geodesics in the sense of [Mj05b] and those in the present paper differ slightly. The difference is due to the grafting annulus $A_\sigma$ that we use here in place of $\sigma$. What is interesting is that whether we electrocute $\sigma$ (to obtain $\mathcal{S}_{el}$) or its complementary components (to obtain $\mathcal{S}_{Gel}$), we obtain very nearly the same electro-ambient geodesics. In fact modulo $c$, they are the same.

We now recall a Lemma from [Mj05b]:

**Lemma 3.4.** (See Lemma 3.7 of [Mj05b]) There exists $(K, \epsilon)$ such that each electro-ambient representative $\lambda_{el}$ of an electric geodesic in $\tilde{\mathcal{S}}_{el}$ is a $(K, \epsilon)$ hyperbolic quasigeodesic.

Since $\tilde{c}$ is clearly a quasi-isometry, it follows easily that:

**Lemma 3.5.** There exists $(K, \epsilon)$ such that each electro-ambient representative $\lambda_{Gel}$ of an electric geodesic in $\tilde{\mathcal{S}}_{Gel}$ is a $(K, \epsilon)$ hyperbolic quasigeodesic.

In the above form, **electro-ambient quasigeodesics** are considered only in the context of surfaces, closed geodesics on them and their complementary (amalgamation) components. A considerable generalization of this was obtained in [Mj05b], which will be necessary while considering the global geometry of $\tilde{M}$ (rather than the geometry of $\tilde{B}$, for an amalgamated building block $B$).
Definition 3.6. Given a collection $H$ of $C$-quasiconvex, $D$-separated sets and a number $\epsilon$ we shall say that a geodesic (resp. quasigeodesic) $\gamma$ is a geodesic (resp. quasigeodesic) without backtracking with respect to $\epsilon$ neighborhoods if $\gamma$ does not return to $N_\epsilon(H)$ after leaving it, for any $H \in H$. A geodesic (resp. quasigeodesic) $\gamma$ is a geodesic (resp. quasigeodesic) without backtracking if it is a geodesic (resp. quasigeodesic) without backtracking with respect to $\epsilon$ neighborhoods for some $\epsilon \geq 0$.

Note: For strictly convex sets, $\epsilon = 0$ suffices, whereas for convex sets any $\epsilon > 0$ is enough.

Let $X$ be a $\delta$-hyperbolic metric space, and $H$ a family of $C$-quasiconvex, $D$-separated collection of subsets. Then by Lemma 3.3, $X_{el}$ obtained by electrocuting the subsets in $H$ is a $\Delta = \Delta(\delta, C, D)$ -hyperbolic metric space. Now, let $\alpha = [a, b]$ be a hyperbolic geodesic in $X$ and $\beta$ be an electric $P$-quasigeodesic without backtracking joining $a, b$. Replace each maximal subsegment, (with end-points $p, q$, say) starting from the left of $\beta$ lying within some $H \in H$ by a hyperbolic geodesic $[p, q]$. The resulting connected path $\beta_q$ is called an electro-ambient representative in $X$.

In [Mj05b] we noted that $\beta_q$ need not be a hyperbolic quasigeodesic. However, we did adapt Proposition 4.3 of Klarreich [Kla99] to obtain the following:

Lemma 3.7. (See Proposition 4.3 of [Kla99], also see Lemma 3.10 of [Mj05b]) Given $\delta, C, D, P$ there exists $C_3$ such that the following holds:
Let $(X, d)$ be a $\delta$-hyperbolic metric space and $H$ a family of $C$-quasiconvex, $D$-separated collection of quasiconvex subsets. Let $(X, d_{el})$ denote the electric space obtained by electrocuting elements of $H$. Then, if $\alpha, \beta_q$ denote respectively a hyperbolic geodesic and an electro-ambient $P$-quasigeodesic with the same end-points, then $\alpha$ lies in a (hyperbolic) $C_3$ neighborhood of $\beta_q$.

Note: The above Lemma will be needed while considering geodesics in $\tilde{M}$.

3.2. Electric isometries. Recall that $S_G$ is a grafted surface obtained from a (fixed) hyperbolic metric by grafting an annulus $A_\sigma$ in place of a geodesic $\sigma$.

Now let $\phi$ be any diffeomorphism of $S_G$ that fixes $A_\sigma$ pointwise and (in case $(S_G - A_\sigma)$ has two components) preserves each amalgamation component as a set, i.e. $\phi$ sends each amalgamation component to itself. Such a $\phi$ will be called a component preserving diffeomorphism. Then in the electrocuted surface $S_{G_{el}}$, any electric geodesic has length equal to the number of times it crosses $A_\sigma$. It follows that $\phi$ is an isometry of $S_{G_{el}}$. (See Lemma 3.12 of [Mj05b] for an analogous result in $S_{el}$.) We state this below.

Lemma 3.8. Let $\phi$ denote a component preserving diffeomorphism of $S_G$. Then $\phi$ induces an isometry of $(S_{G_{el}}, d_{G_{el}})$.

Everything in the above can be lifted to the universal cover $\tilde{S}_{G_{el}}$. We let $\tilde{\phi}$ denote the lift of $\phi$ to $\tilde{S}_{G_{el}}$. This gives

Lemma 3.9. Let $\tilde{\phi}$ denote a lift of a component preserving diffeomorphism $\phi$ to $(\tilde{S}_{G_{el}}, d_{G_{el}})$. Then $\tilde{\phi}$ induces an isometry of $(\tilde{S}_{G_{el}}, d_{G_{el}})$. 

3.3. Nearest-point Projections. We need the following basic lemmas from [Mit98b] and [Mj05b].

The following Lemma says nearest point projections in a $\delta$-hyperbolic metric space do not increase distances much.

**Lemma 3.10.** (Lemma 3.1 of [Mit98b]) Let $(Y,d)$ be a $\delta$-hyperbolic metric space and let $\mu \subset Y$ be a $C$-quasiconvex subset, e.g. a geodesic segment. Let $\pi : Y \rightarrow \mu$ map $y \in Y$ to a point on $\mu$ nearest to $y$. Then $d(\pi(x),\pi(y)) \leq C_3 d(x,y)$ for all $x,y \in Y$ where $C_3$ depends only on $\delta,C$.

The next lemma says that quasi-isometries and nearest-point projections on hyperbolic metric spaces ‘almost commute’.

**Lemma 3.11.** (Lemma 3.5 of [Mit98b]) Suppose $(Y_1,d_1)$ and $(Y_2,d_2)$ are $\delta$-hyperbolic. Let $\mu_1$ be some geodesic segment in $Y_1$ joining $a,b$ and let $p$ be any vertex of $Y_1$. Also let $q$ be a vertex on $\mu_1$ such that $d_1(p,q) \leq d_2(p,x)$ for $x \in \mu_1$. Let $\phi$ be a $(K,\epsilon)$ - quasisymmetric embedding from $Y_1$ to $Y_2$. Let $\mu_2$ be a geodesic segment in $Y_2$ joining $\phi(a)$ to $\phi(b)$. Let $r$ be a point on $\mu_2$ such that $d_2(\phi(p),r) \leq d_2(\phi(p),x)$ for $x \in \mu_2$. Then $d_2(r,\phi(q)) \leq C_4$ for some constant $C_4$ depending only on $K,\epsilon$ and $\delta$.

For our purposes we shall need the above Lemma for quasi-isometries from $\tilde{S_a}$ to $\tilde{S_b}$ for two different hyperbolic structures on the same surface. We shall also need it for electrocuted surfaces.

Yet another property that we shall require for nearest point projections is that nearest point projections in the electric metric and in the ‘almost hyperbolic’ metric (coming as a lift of the metric on $S_G$) almost agree. Let $S_G = Y$ be the universal cover of a surface with the grafted metric. Equip $Y$ with the path metric $d$ as usual. Then $Y$ is quasi-isometric to the hyperbolic plane. Recall that $d_G$ denotes the electric metric on $Y$ obtained by electrocuting the lifts of complementary components. Now, let $\mu = [a,b]$ be a geodesic on $(Y,d)$ and let $\mu_q$ denote the electro-ambient quasigeodesic joining $a,b$ (See Lemma 3.4). Let $\pi$ denote the nearest point projection in $(Y,d)$. Tentatively, let $\pi_e$ denote the nearest point projection in $(Y,d_G)$. Note that $\pi_e$ is not well-defined. It is defined up to a bounded amount of discrepancy in the electric metric $d_G$. But we would like to make $\pi_e$ well-defined up to a bounded amount of discrepancy in the metric $d$.

**Definition 3.12.** Let $y \in Y$ and let $\mu_q$ be an electro-ambient representative of an electric geodesic $\mu_G$ in $(Y,d_G)$. Then $\pi_e(y) = z \in \mu_q$ if the ordered pair $\{d_G(z,\pi_e(y)),d(y,\pi_e(y))\}$ is minimized at $z$.

The proof of the following Lemma shows that this gives us a definition of $\pi_e$ which is ambiguous by a finite amount of discrepancy not only in the electric metric but also in the hyperbolic metric.

**Lemma 3.13.** There exists $C > 0$ such that the following holds. Let $\mu$ be a hyperbolic geodesic joining $a,b$. Let $\mu_G$ be an electric geodesic joining $a,b$. Also let $\mu_q$ be the electro-ambient representative of $\mu_G$. Let $\pi_e$ denote the nearest point projection of $Y$ onto $\mu$. $d(\pi_e(y),\pi_e(y))$ is uniformly bounded.

**Proof:** This Lemma is similar to Lemma 3.16 of [Mj05b], but its proof is somewhat different. For the purposes of this lemma we shall refer to the metric on $S_G$ as the hyperbolic metric whereas it is in fact only quasi-isometric to it.
[u, v] and [u, v] will denote respectively the hyperbolic geodesic and the electroambient quasi-geodesic joining u, v. Since [u, v] is a quasi-geodesic by Lemma 3.4, it suffices to show that for any y, its hyperbolic and electric projections π_h(y), π_e(y) almost agree.

First note that any hyperbolic geodesic η in \( \tilde{S}_G \) is also an electric geodesic. This follows from the fact that \( (\tilde{S}_G, d_G) \) maps to a tree T (arising from the splitting along σ) with the pullback of every vertex a set of diameter zero in the pseudometric \( d_G \). Now if a path in \( \tilde{S}_G \) projects to a path in T that is not a geodesic, then it must backtrack. Hence, it must leave an amalgamating component and return to it. Such a path can clearly not be a hyperbolic geodesic in \( \tilde{S}_G \) (since each amalgamating component is convex).

Next, it follows that hyperbolic projections automatically minimize electric distances. Else as in the preceding paragraph, [y, π_h(y)] would have to cut a lift of \( \tilde{\sigma} = \tilde{\sigma}_1 \) that separates [u, v]q. Further, [y, π_h(y)] cannot return to \( \tilde{\sigma}_1 \) after leaving it. Let z be the first point at which [y, π_h(y)] meets \( \tilde{\sigma}_1 \). Also let w be the point on [u, v]q ∩ \( \tilde{\sigma}_1 \) that is nearest to z. Since amalgamation segments of [u, v]q meeting \( \tilde{\sigma}_1 \) are perpendicular to the latter, it follows that \( d(w, z) < d(w, \pi_h(y)) \) and therefore \( d(y, z) < d(y, \pi_h(y)) \) contradicting the definition of \( \pi_h(y) \). Hence hyperbolic projections automatically minimize electric distances.

Further, it follows by repeating the argument in the first paragraph that [y, π_h(y)] and [y, π_e(y)] pass through the same set of amalgamation components in the same order; in particular they cut across the same set of lifts of \( \tilde{\sigma} \). Let \( \tilde{\sigma}_2 \) be the last such lift. Then \( \tilde{\sigma}_2 \) forms the boundary of an amalgamation component \( \tilde{S}_A \) whose intersection with \( [u, v]_q \) is of the form \([a, b] \cup [b, c] \cup [c, d]\), where \([a, b] \subset \tilde{\sigma}_3 \) and \([c, d] \subset \tilde{\sigma}_4 \) are subsegments of two lifts of \( \sigma \) and \([b, c]\) is perpendicular to these two. Then the nearest-point projection of \( \tilde{\sigma}_2 \) onto each of \([a, b], [b, c], [c, d]\) has uniformly bounded diameter. Hence the nearest point projection of \( \tilde{\sigma}_2 \) onto the hyperbolic geodesic \([a, d] \subset \tilde{S}_A \) has uniformly bounded diameter. The result follows. □

### 3.4. Coboundedness and Consequences

In this Section, we collect together a few more results that strengthen Lemmas 3.2 and 3.3.

**Definition 3.14.** A collection \( \mathcal{H} \) of uniformly C-quasiconvex sets in a \( \delta \)-hyperbolic metric space \( X \) is said to be **mutually D-cobounded** if for all \( H_i, H_j \in \mathcal{H}, \pi_i(H_j) \) has diameter less than \( D \), where \( \pi_i \) denotes a nearest point projection of \( X \) onto \( H_i \). A collection is **mutually cobounded** if it is mutually D-cobounded for some \( D \).

**Lemma 3.15.** Suppose \( X \) is a \( \delta \)-hyperbolic metric space with a collection \( \mathcal{H} \) of C-quasiconvex \( K \)-separated \( D \)-mutually cobounded subsets. There exists \( c_0 = c_0(C, K, D, \delta) \) such that the following holds:

Let \( \beta \) be an electric \( P \)-quasi-geodesic without backtracking and \( \gamma \) a hyperbolic geodesic, both joining \( x, y \). Then, given \( \epsilon \geq c_0 \) there exists \( D = D(P, \epsilon) \) such that

1. **Similar Intersection Patterns 1:** if precisely one of \( \{\beta, \gamma\} \) meets an \( \epsilon \)-neighborhood \( N_\epsilon(H_1) \) of an electrocuted quasiconvex set \( H_1 \in \mathcal{H} \), then the length (measured in the intrinsic path-metric on \( N_\epsilon(H_1) \)) from the entry point to the exit point is at most \( D \).
Similar Intersection Patterns 2: if both \( \{ \beta, \gamma \} \) meet some \( N_\varepsilon(H_1) \) then the length (measured in the intrinsic path-metric on \( N_\varepsilon(H_1) \)) from the entry point of \( \beta \) to that of \( \gamma \) is at most \( D \); similarly for exit points.

Summarizing, we have:

- If \( X \) is a hyperbolic metric space and \( H \) a collection of uniformly quasiconvex mutually cobounded separated subsets, then \( X \) is hyperbolic relative to the collection \( H \) and satisfies Bounded Penetration, i.e. hyperbolic geodesics and electric quasigeodesics have similar intersection patterns in the sense of Lemma 3.15.

The relevance of co-boundedness comes from the following Lemma which is essentially due to Farb [Far98].

**Lemma 3.16.** Let \( M^h \) be a hyperbolic manifold of \( i \)-bounded geometry, with Margulis tubes \( T_i \in T \) and horoballs \( H_j \in H \). Then the lifts \( \tilde{T}_i \) and \( \tilde{H}_j \) are mutually co-bounded.

The proof given in [Far98] is for a collection of separated horospheres, but the same proof works for neighborhoods of geodesics and horospheres as well.

A closely related theorem was proved by McMullen (Theorem 8.1 of [McM01]). As usual, \( N_R(Z) \) will denote the \( R \)-neighborhood of the set \( Z \).

**Definition 3.17.** The \( \varepsilon \)-neighborhood of a bi-infinite geodesic in \( \mathbb{H}^n \) will be called a thickened geodesic.

**Theorem 3.18.** [McM01] Let \( \gamma : I \to X \setminus \bigcup H \) be an ambient \( K \)-quasigeodesic (for \( X \) a convex subset of \( \mathbb{H}^n \)) and let \( H \) denote a uniformly separated collection of horoballs and thickened geodesics. Let \( \eta \) be the hyperbolic geodesic with the same endpoints as \( \gamma \). Let \( H(\eta) \) be the union of all the horoballs and thickened geodesics in \( H \) meeting \( \eta \). Then \( \eta \cup H(\eta) \) is (uniformly) quasiconvex and \( \gamma(I) \subset B(\eta \cup H(\eta)) \), where \( R \) depends only on \( K \).

4. Universal Covers of Building Blocks and Electric Geometry

4.1. Graph Model of Building Blocks. Amalgamation Blocks

Given a geodesic segment \( \lambda \subset \tilde{S} \) and a basic amalgamation building block \( B \), let \( \lambda = [a, b] \subset \tilde{S} \times \{0\} \) be a geodesic segment, where \( \tilde{S} \times \{0\} \subset \tilde{B} \).

We shall now build a graph model for \( \tilde{B} \) which will be quasi-isometric to an electrocuted version of the original model, where amalgamation components of the geometric core \( K \) are electrocuted.

\( \tilde{S} \times \{0\} \) and \( \tilde{S} \times \{3\} \) are equipped with hyperbolic metrics. \( \tilde{S} \times \{1\} \) and \( \tilde{S} \times \{2\} \) are grafted surfaces with electric metric obtained by electrocuting the amalgamation components. This constructs 4 ‘sheets’ of \( \tilde{S} \) comprising the ‘horizontal skeleton’ of the ‘graph model’ of \( \tilde{B} \). Now for the vertical strands. On each vertical element of the form \( x \times [0, 1] \) and \( x \times [2, 3] \) put the Euclidean metric.

To do this precisely, one needs to take a bit more care and perform the construction in the universal cover. For each amalgamation component of \( \tilde{K} \) (recall that
such a component is a lift of an amalgamation component of $K$ to the universal cover along with bounding lifts $\tilde{T}_\sigma$ of the Margulis tubes. For each such component $\tilde{K}_i$ we construct $\tilde{K}_i \times [0,1/2]$, so that any two copies $\tilde{K}_i \times [0,1/2]$ intersect (if at all they do) only along the original bounding lifts $\tilde{T}_\sigma$ of the Margulis tubes. In particular the copies $\tilde{K}_i \times [0,1/2]$ intersect $\tilde{K}_j \times [0,1/2]$ along $\tilde{K}_i \times \{0\}$. Next put the zero metric on each copy of $\tilde{K}_i \times \{1/2\}$.

This construction is very closely related to the ‘coning’ construction introduced by Farb in [Far98].

The resulting copy of $\tilde{B}$ will be called the graph model of an amalgamation block.

Next, we give an $I$-bundle structure to $K$ that preserves the grafting annulus. Thus $A_\sigma \times [1,2]$ has a structure of a Margulis tube. Let $\phi$ denote a map from $S \times \{1\}$ to $S \times \{2\}$ mapping $(x,1)$ to $(x,2)$. Clearly there is a bound $l_B$ on the length in $K$ of $x \times [1,2]$ as $x$ ranges over $S \times \{1\}$. That is to say that the core $K$ has a bounded thickness. This bound depends on the block $B$ we are considering.

Let $\tilde{\phi}$ denote the lift of $\phi$ to $\tilde{K}$. Then $\tilde{\phi}$ is a $(k,\epsilon)$-quasi-isometry where $k, \epsilon$ depend on the block $B$.

Thick Block

For a thick block $B = \tilde{S} \times [0,1]$, recall that $B$ is the universal curve over a ‘thick’ Teichmuller geodesic $\lambda_{Teich} = [a,b]$ of length less than some fixed $D > 0$. Each $S \times \{x\}$ is identified with the hyperbolic surface over $(a + \frac{x}{2\pi})$ (assuming that the Teichmuller geodesic is parametrized by arc-length).

Here $S \times \{0\}$ is identified with the hyperbolic surface corresponding to $a$, $S \times \{1\}$ is identified with the hyperbolic surface corresponding to $b$ and each $(x,a)$ is joined to $(x,b)$ by a segment of length 1.

The resulting model of $\tilde{B}$ is called a graph model of a thick block. Metrics on graph models are called graph metrics.

Admissible Paths

Admissible paths consist of the following:

1) Horizontal segments along some $\tilde{S} \times \{i\}$ for $i = \{0,1,2,3\}$ (amalgamated blocks) or $i = \{0,1\}$ (thick blocks).
2) Vertical segments $x \times [0,1]$ or $x \times [2,3]$ for amalgamated blocks or $x \times [0,1]$ for thick blocks.
3) Vertical segments of length $\leq l_B$ joining $x \times \{1\}$ to $x \times \{2\}$ for amalgamated blocks.

4.2. Construction of Quasiconvex Sets for Building Blocks. In the next section, we will construct a set $B_\lambda$ containing $\lambda$ and a retraction $\Pi_\lambda$ of $\tilde{M}$ onto it. $\Pi_\lambda$ will have the property that it does not stretch distances much. This will show that $B_\lambda$ is quasi-isometrically embedded in $\tilde{M}$.

In this subsection, we describe the construction of $B_\lambda$ restricted to a building block $B$.

Construction of $B_\lambda(B)$ - Thick Block

Let the thick block be the universal curve over a Teichmuller geodesic $[\alpha,\beta]$. Let $S_\alpha$ denote the hyperbolic surface over $\alpha$ and $S_\beta$ denote the hyperbolic surface over $\beta$. 
First, let \( \lambda = [a,b] \) be a geodesic segment in \( \tilde{S} \). Let \( \lambda_{B0} \) denote \( \lambda \times \{0\} \).

Next, let \( \psi \) be the lift of the 'identity' map from \( S_\alpha \) to \( \tilde{S} \). Let \( \Psi \) denote the induced map on geodesics and let \( \Psi(\lambda) \) denote the hyperbolic geodesic joining \( \psi(a), \psi(b) \). Let \( \lambda_{B1} \) denote \( \Psi(\lambda) \times \{1\} \).

For the universal cover \( \tilde{B} \) of the thick block \( B \), define:
\[
B_\lambda(B) = \bigcup_{i=0,1} \lambda_{Bi}
\]

**Definition 4.1.** Each \( \tilde{S} \times i \) for \( i = 0,1 \) will be called a horizontal sheet of \( \tilde{B} \) when \( B \) is a thick block.

**Construction of** \( B_\lambda(B) \) - **Amalgamation Block**

First, recall that \( \lambda = [a,b] \) is a geodesic segment in \( \tilde{S} \). Let \( \lambda_{B0} \) denote \( \lambda \times \{0\} \).

Next, let \( \lambda_{Gel} \) denote the electric geodesic joining \( a,b \) in the electric pseudo-metric on \( \tilde{S} \) obtained by electrocuting lifts of \( \sigma \). Let \( \lambda_{B1} \) denote \( \lambda_{Gel} \times \{1\} \).

Third, recall that \( \phi \) is the lift of a component preserving diffeomorphism \( \phi \) to \( \tilde{S} \) equipped with the electric metric \( d_{Gel} \). Let \( \Phi \) denote the induced map on geodesics, i.e., if \( \mu = [x,y] \subset (\tilde{S},d_{Gel}) \), then \( \Phi(\mu) = [\phi(x),\phi(y)] \) is the geodesic joining \( \phi(x),\phi(y) \). Let \( \lambda_{B2} \) denote \( \Phi(\lambda_{Gel}) \times \{2\} \).

Fourthly, let \( \Phi(\lambda) \) denote the hyperbolic geodesic joining \( \phi(a),\phi(b) \). Let \( \lambda_{B3} \) denote \( \Phi(\lambda) \times \{3\} \).

For the universal cover \( \tilde{B} \) of the thin block \( B \), define:
\[
B_\lambda(B) = \bigcup_{i=0,\ldots,3} \lambda_{Bi}
\]

**Definition 4.2.** Each \( \tilde{S} \times i \) for \( i = 0 \cdots 3 \) will be called a horizontal sheet of \( \tilde{B} \) when \( B \) is a thick block.

**Construction of** \( \Pi_{\lambda,B} \) - **Thick Block**

On \( \tilde{S} \times \{0\} \), let \( \Pi_{B0} \) denote nearest point projection onto \( \lambda_{B0} \) in the path metric on \( \tilde{S} \times \{0\} \).

On \( \tilde{S} \times \{1\} \), let \( \Pi_{B1} \) denote nearest point projection onto \( \lambda_{B1} \) in the path metric on \( \tilde{S} \times \{1\} \).

For the universal cover \( \tilde{B} \) of the thick block \( B \), define:
\[
\Pi_{\lambda,B}(x) = \Pi_{Bi}(x), x \in \tilde{S} \times \{i\}, i = 0,1
\]

**Construction of** \( \Pi_{\lambda,B} \) - **Amalgamation Block**

On \( \tilde{S} \times \{0\} \), let \( \Pi_{B0} \) denote nearest point projection onto \( \lambda_{B0} \). Here the nearest point projection is taken in the path metric on \( \tilde{S} \times \{0\} \) which is a hyperbolic metric space.

On \( \tilde{S} \times \{1\} \), let \( \Pi_{B1} \) denote the nearest point projection onto \( \lambda_{B1} \). Here the nearest point projection is taken in the sense of the definition preceding Lemma 3.13, i.e., minimizing the ordered pair \( (d_{Gel},d_{hyp}) \) (where \( d_{Gel},d_{hyp} \) refer to electric and hyperbolic metrics respectively.)

On \( \tilde{S} \times \{2\} \), let \( \Pi_{B2} \) denote the nearest point projection onto \( \lambda_{B2} \). Here, again the nearest point projection is taken in the sense of the definition preceding Lemma 3.13.

Again, on \( \tilde{S} \times \{3\} \), let \( \Pi_{B3} \) denote nearest point projection onto \( \lambda_{B3} \). Here the nearest point projection is taken in the path metric on \( \tilde{S} \times \{3\} \) which is a hyperbolic metric space.
For the universal cover $\tilde{B}$ of the thin block $B$, define:

$$\Pi_{\lambda,B}(x) = \Pi_{B_i}(x), x \in \tilde{S} \times \{i\}, i = 0, \ldots, 3$$

$\Pi_{\lambda,B}$ is a retract - Thick Block

The proof for a thick block is exactly as in [Mit98b] and [Mj05b]. We omit it here.

**Lemma 4.3.** (Lemma 4.1 of [Mj05b]) There exists $C > 0$ such that the following holds:

Let $x, y \in \tilde{S} \times \{0, 1\} \subset \tilde{B}$ for some thick block $B$. Then $d(\Pi_{\lambda,B}(x), \Pi_{\lambda,B}(y)) \leq Cd(x,y)$.

$\Pi_{\lambda,B}$ is a retract - Amalgamation Block

The main ingredient in this case is Lemma 3.13.

**Lemma 4.4.** There exists $C > 0$ such that the following holds:

Let $x, y \in \tilde{S} \times \{0, 1, 2, 3\} \subset \tilde{B}$ for some amalgamated block $B$. Then $d_{Gel}(\Pi_{\lambda,B}(x), \Pi_{\lambda,B}(y)) \leq C d_{Gel}(x,y)$.

**Proof:** It is enough to show this for the following cases:

1) $x, y \in \tilde{S} \times \{0\}$ OR $x, y \in \tilde{S} \times \{3\}$.
2) $x = (p, 0)$ and $y = (p, 1)$ for some $p$
3) $x, y$ both lie in the geometric core $K$
4) $x = (p, 2)$ and $y = (p, 3)$ for some $p$.

**Case 1:** This follows from Lemma 3.10

**Case 2 and Case 4:** These follow from Lemma 3.13 which says that the hyperbolic and electric projections of $p$ onto the hyperbolic geodesic $[a,b]$ and the electro-ambient geodesic $[a,b]_{ea}$ respectively ‘almost agree’. If $\pi_h$ and $\pi_e$ denote the hyperbolic and electric projections, then there exists $C_1 > 0$ such that

$$d_{Gel}(\pi_h(p), \pi_e(p)) \leq C_1$$

Hence

$$d_{Gel}(\Pi_{\lambda,B}((p, i)), \Pi_{\lambda,B}((p, i + 1))) \leq C_1 + 1, \text{ for } i = 0, 2.$$

**Case 3:** This follows from the fact that $K$ in the graph model with the electric metric is essentially the tree coming from the splitting. Further, by the properties of $\pi_e$, each amalgamation component projects down to a set of diameter zero. Hence

$$d_{Gel}(\Pi_{\lambda,B}(p), \Pi_{\lambda,B}(q)) \leq C_1 + 1$$

Choosing $C$ as the maximum of these constants, we are through. \(\square\)

5. Construction of Quasiconvex Sets and Quasigeodesics

5.1. Construction of $B_\lambda$ and $\Pi_\lambda$. Given a manifold $M$ of amalgamated geometry, we know that $M$ is homeomorphic to $S \times J$ for $J = [0, \infty)$ or $(-\infty, \infty)$. By definition of amalgamated geometry, there exists a sequence $I_i$ of intervals and blocks $B_i$ where the metric on $S \times I_i$ coincides with that on some building block $B_i$. Denote:

- $B_{i\mu} = B_i$
- $\Pi_{i\mu} = \Pi_i$
Now for a block $B = S \times I$ (thick or amalgamated), a natural map $\Phi_B$ may be defined taking $\mu = B_{\mu, B} \cap \tilde{S} \times \{0\}$ to a geodesic $B_{\mu, B} \cap \tilde{S} \times \{k\} = \Phi_B(\mu)$ where $k = 1$ or 3 according as $B$ is thick or amalgamated. Let the map $\Phi_{B_i}$ be denoted as $\Phi_i$ for $i \geq 0$. For $i < 0$ we shall modify this by defining $\Phi_i$ to be the map that takes $\mu = B_{\mu, B_i} \cap \tilde{S} \times \{k\}$ to a geodesic $B_{\mu, B_i} \cap \tilde{S} \times \{0\} = \Phi_i(\mu)$ where $k = 1$ or 3 according as $B$ is thick or amalgamated.

We start with a reference block $B_0$ and a reference geodesic segment $\lambda = \lambda_0$ on the ‘lower surface’ $\tilde{S} \times \{0\}$. Now inductively define:

- $\lambda_{i+1} = \Phi_i(\lambda_i)$ for $i \geq 0$
- $\lambda_{i-1} = \Phi_i(\lambda_i)$ for $i \leq 0$
- $B_{\lambda_i} = B_{\lambda_i}(B_i)$
- $\Pi_\lambda = \Pi_{\lambda_i}^{B_i_i}$
- $B_\lambda = \bigcup B_{\lambda_i}$
- $\Pi_\lambda = \bigcup \Pi_{\lambda_i}$

Recall that each $\tilde{S} \times i$ for $i = 0 \cdots m$ is called a horizontal sheet of $\tilde{B}$, where $m = 1$ or 3 according as $B$ is thick or amalgamated. We will restrict our attention to the union of the horizontal sheets $\tilde{M_H}$ of $\tilde{M}$ with the metric induced from the graph model.

Clearly, $B_\lambda \subset \tilde{M_H} \subset \tilde{M}$, and $\Pi_\lambda$ is defined from $\tilde{M_H}$ to $B_\lambda$. Since $\tilde{M_H}$ is a ‘coarse net’ in $\tilde{M}$ (equipped with the graph model metric), we will be able to get all the coarse information we need by restricting ourselves to $\tilde{M_H}$.

By Lemmas 4.3 and 4.4, we obtain the fact that each $\Pi_{\lambda_i}$ is a retract. Hence assembling all these retracts together, we have the following basic theorem:

**Theorem 5.1.** There exists $C > 0$ such that for any geodesic $\lambda = \lambda_0 \subset \tilde{S} \times \{0\} \subset B_0$, the retraction $\Pi_\lambda : \tilde{M_H} \to B_\lambda$ satisfies:

$$d_{\text{gel}}(\Pi_{\lambda, B}(x), \Pi_{\lambda, B}(y)) \leq C d_{\text{gel}}(x, y) + C.$$

**Note 1** For Theorem 5.1 above, note that all that we really require is that the universal cover $\tilde{S}$ be a hyperbolic metric space. There is no restriction on $\tilde{M_H}$. In fact, Theorem 5.1 would hold for general stacks of hyperbolic metric spaces with blocks of amalgamated geometry.

**Note 2:** $\tilde{M_H}$ has been built up out of graph models of thick and amalgamated blocks and have sheets that are electrocuted along geodesics.

We want to make Note 1 above explicit. We first modify the definition of amalgamation geometry as follows, retaining only local quasiconvexity.

**Definition:** A manifold $M$ homeomorphic to $S \times J$, where $J = [0, \infty)$ or $J = (-\infty, \infty)$, is said to be a model of weak amalgamation geometry if

1) there is a fiber-preserving homeomorphism from $M$ to $S \times J$ that lifts to a quasi-isometry of universal covers
2) there exists a sequence $I_i$ of intervals (with disjoint interiors) and blocks $B_i$ where the metric on $S \times I_i$ is the same as that on some building block $B_i$. Each block is either thick or has amalgamation geometry.
3) $\bigcup I_i = J$
4) There exists $C_0 > 0$ such that for all amalgamated blocks $B_i$ and geometric cores $C \subset B_i$, all amalgamation components of $C$ are $C_0$-quasiconvex in $B_i$.
Corollary 5.2. Let $M$ be a model manifold of weak amalgamation geometry. There exists $C > 0$ such that the following holds:

Given any geodesic $\lambda \subset S \times \{0\}$, let $B_\lambda$, $\Pi_\lambda$ be as before. Then for $\lambda = \lambda_0 \subset \tilde{S} \times \{0\} \subset \tilde{B}_0$, the retraction $\Pi_\lambda : \tilde{M}_H \to B_\lambda$ satisfies:

$$d_{\text{Gel}}(\Pi_\lambda(x), \Pi_\lambda(y)) \leq C d_{\text{Gel}}(x, y) + C.$$ 

In fact, all that follows in this section may just as well be done for model manifolds of weak amalgamation geometry. We shall make this explicit again at the end of this entire section.

But before we proceed, we would like to deduce one further Corollary of Theorem 5.1, which shall be useful towards the end of the paper. Instead of constructing vertical hyperbolic ladders $B_\lambda$ for finite geodesic segments, first note that $\lambda$ might as well be bi-infinite. Next, we would like to construct such a $B_\lambda$ equivariantly under the action of $\mathbb{Z}$. That is to say, we would like to construct a vertical annulus in the manifold $M$ homeomorphic to $S \times \mathbb{R}$.

To do this, we start with a simple closed geodesic $\sigma$ on $S \times \{0\}$. Instead of performing the construction in the universal cover, homotop $\sigma$ into $S \times \{i\}$ for each level $i$. Let $\tilde{\sigma}_i$ denote the shortest electro-ambient geodesic in the free homotopy class of $\sigma \times \{i\}$ in the path pseudometric on $S \times \{i\}$. Now let $B_\sigma$ denote the set $B_\sigma = \bigcup \tilde{\sigma}_i$. Then the proof of Theorem 5.1 ensures the quasiconvexity of $B_\sigma$ in the graph-metric. Finally, since $B_\sigma$ has been constructed to be equivariant under the action of the surface group, its quotient in $M$ is an embedded ‘quasi-annulus’ $A_{P_\sigma}$ which partitions the manifold locally. We use the term ‘quasi-annulus’ because $A_{P_\sigma}$ is a collection of disjoint circles at different levels. We finally conclude:

Corollary 5.3. Let $M$ be a model manifold of weak amalgamation geometry. There exists $C > 0$ such that the following holds:

Given any simple closed geodesic $\sigma \subset S \times \{0\}$, let $B_\sigma$ be as above. Then its quotient, the embedded quasi-annulus $A_{P_\sigma}$ above is $C$-quasiconvex in $M$ with the graph metric.

Another Corollary will be used later. Suppose $\Sigma = \Sigma \times \{0\}$ be a subsurface of $S \times \{0\}$ with geodesic boundary components $\sigma^1 \cdots \sigma^k$. Let $\Sigma_i$ be the subsurface of $S \times \{i\}$ that is bounded by $\sigma_i^1 \cdots \sigma_i^l$. Let $B_\Sigma = \bigcup \Sigma_i$.

Corollary 5.4. Let $M$ be a model manifold of weak amalgamation geometry. There exists $C > 0$ such that the following holds:

Given any subsurface $\Sigma \subset S \times \{0\}$ with geodesic boundary components, let $B_\Sigma$ be as above. Then $B_\Sigma$ is $C$-quasiconvex in $M$ with the graph metric.

5.2. Heights of Blocks. Recall that each geometric core $C \subset B$ is identified with $S \times I$ where each fibre $\{x\} \times I$ has length $\leq l_C$ for some $l_C$, called the thickness of the block $B$. If $C \subset B_i$, for one of the above blocks $B_i$, we shall denote $l_C$ as $l_i$.

Instead of considering all the horizontal sheets, we would now like to consider only the boundary horizontal sheets, i.e. for a thick block we consider $\tilde{S} \times \{0, 1\}$ and for a thin block we consider $\tilde{S} \times \{0, 3\}$. The union of all boundary horizontal sheets will be denoted by $M_{BH}$. 
Observation 1: \( \tilde{M}_{BH} \) is a ‘coarse net’ in \( \tilde{M} \) in the graph model, but not in the model of amalgamated geometry.

In the graph model, any point can be connected by a vertical segment of length \( \leq 2 \) to one of the boundary horizontal sheets. However, in the model of amalgamated geometry, there are points within amalgamation components which are at a distance of the order of \( l_i \) from the boundary horizontal sheets. Since \( l_i \) is arbitrary, \( \tilde{M}_{BH} \) is no longer a ‘coarse net’ in \( \tilde{M} \) equipped with the model of amalgamated geometry.

Observation 2: \( \tilde{M}_H \) is defined only in the graph model, but not in the model of amalgamated geometry.

Observation 3: The electric metric on the model of amalgamated geometry on \( \tilde{M} \) obtained by electrocuting amalgamation components is quasi-isometric to the graph model of \( \tilde{M} \).

Bounded Height of Thick Block

Let \( \mu \subset \tilde{S} \times \{0\} \tilde{B}_i \) be a geodesic in a (thick or amalgamated) block. Then there exists a \( (K_i, \epsilon_i) \)- quasi-isometry \( \psi_i \) ( = \( \phi_i \) for thick blocks) from \( \tilde{S} \times \{0\} \) to \( \tilde{S} \times \{1\} \) and \( \Psi_i \) is the induced map on geodesics. Hence, for any \( x \in \mu \), \( \psi_i(x) \) lies within some bounded distance \( C_i \) of \( \Psi_i(\mu) \). But \( x \) is connected to \( \psi_i(x) \) by

Case 1 - Thick Blocks: a vertical segment of length 1
Case 2 - Amalgamated Blocks: the union of
1) two vertical segments of length 1 between \( \tilde{S} \times \{i\} \) and \( \tilde{S} \times \{i+1\} \) for \( i = 0, 2 \)
2) a horizontal segment of length bounded by (some uniform) \( C' \) (cf. Lemma 3.4) connecting \( (x, 1) \) to a point on the electro-ambient geodesic \( B_\lambda(B) \cap \tilde{S} \times \{1\} \)
3) a vertical segment of electric length zero in the graph model connecting \( (x, 1) \) to \( (x, 2) \). Such a path has to travel through an amalgamated block in the model of amalgamated geometry and has length less than \( l_i \), where \( l_i \) is the thickness of the ith block \( B_i \).
4) a horizontal segment of length less than \( C' \) (Lemma 3.4) connecting \( (\phi_i(x), 3) \) to a point on the hyperbolic geodesic \( B_\lambda(B) \cap \tilde{S} \times \{3\} \)

Thus \( x \) can be connected to a point on \( x' \in \Psi_i(\mu) \) by a path of length less than \( g(i) = 2 + 2C' + l_i \). Recall that \( \lambda_i \) is the geodesic on the lower horizontal surface of the block \( B_i \), the same can be done for blocks \( B_{i-1} \) and going down from \( \lambda_i \) to \( \lambda_{i-1} \). What we have thus shown is:

Lemma 5.5. There exists a function \( g: \mathbb{Z} \to \mathbb{N} \) such that for any block \( B_i \) (resp. \( B_{i-1} \)), and \( x \in \lambda_i \), there exists \( x' \in \lambda_{i+1} \) (resp. \( \lambda_{i-1} \)) for \( i \geq 0 \) (resp. \( i \leq 0 \)), satisfying:
\[
d(x, x') \leq g(i)
\]

5.3. Admissible Paths. We want to define a collection of \( B_\lambda \)-elementary admissible paths lying in a bounded neighborhood of \( B_\lambda \). \( B_\lambda \) is not connected. Hence, it does not make much sense to speak of the path-metric on \( B_\lambda \). To remedy this we introduce a ‘thickening’ (cf. [Gro93]) of \( B_\lambda \) which is path-connected and where the paths are controlled. A \( B_\lambda \)-admissible path will be a composition of \( B_\lambda \)-elementary admissible paths.
Recall that admissible paths in the graph model of bounded geometry consist of the following:

1) Horizontal segments along some \( \tilde{S} \times \{i\} \) for \( i = \{0, 1, 2, 3\} \) (amalgamated blocks) or \( i = \{0, 1\} \) (thick blocks).
2) Vertical segments \( x \times [0, 1] \text{ or } x \times [2, 3] \) for amalgamated blocks, where \( x \in \tilde{S} \).
3) Hyperbolic geodesic segments of length \( \leq l_B \) in \( K \subset B \) joining \( x \times \{1\} \) to \( x \times \{2\} \) for amalgamated blocks.
4) Vertical segments of length 1 joining \( x \times \{0\} \) to \( x \times \{1\} \) for thick blocks.

We shall choose a subclass of these admissible paths to define \( B_\lambda \)-elementary admissible paths.

\[ B_\lambda \]-elementary admissible paths in the thick block

Let \( B = S \times [i, i+1] \) be a thick block, where each \( (x, i) \) is connected by a vertical segment of length 1 to \( (x, i+1) \). Let \( \phi \) be the map that takes \( (x, i) \) to \( (x, i+1) \). Also \( \Phi \) is the map on geodesics induced by \( \phi \). Let \( B_\lambda \cap \tilde{B} = \lambda_i \cup \lambda_{i+1} \) where \( \lambda_i \) lies on \( \tilde{S} \times \{i\} \) and \( \lambda_{i+1} \) lies on \( \tilde{S} \times \{i+1\} \). \( \pi_j \), for \( j = i, i+1 \) denote nearest-point projections of \( \tilde{S} \times \{j\} \) onto \( \lambda_j \). Next, since \( \phi \) is a quasi-isometry, there exists \( C > 0 \) such that for all \( (x, i) \in \lambda_i \), \( (x, i+1) \) lies in a \( C \)-neighborhood of \( \Phi(\lambda_i) = \lambda_{i+1} \). The same holds for \( \phi^{-1} \) and points in \( \lambda_{i+1} \), where \( \phi^{-1} \) denotes the quasi-isometric inverse of \( \phi \) from \( \tilde{S} \times \{i+1\} \) to \( \tilde{S} \times \{i\} \). The \( B_\lambda \)-elementary admissible paths in \( \tilde{B} \) consist of the following:

1) Horizontal geodesic subsegments of \( \lambda_j \), \( j = \{i, i+1\} \).
2) Vertical segments of length 1 joining \( x \times \{0\} \) to \( x \times \{1\} \).
3) Horizontal geodesic segments lying in a \( C \)-neighborhood of \( \lambda_j \), \( j = i, i+1 \).

\[ B_\lambda \]-elementary admissible paths in the amalgamated block

Let \( B = S \times [i, i+3] \) be an amalgamated block, where each \( (x, i+1) \) is connected by a geodesic segment of zero electric length and hyperbolic length \( \leq C(B) \) (due to bounded thickness of \( B \)) to \( (\phi(x), i+2) \) (Here \( \phi \) can be thought of as the map from \( \tilde{S} \times \{i+1\} \) to \( \tilde{S} \times \{i+2\} \) that is the identity on the first component. Also \( \Phi \) is the map on canonical representatives of electric geodesics induced by \( \phi \). Let \( B_\lambda \cap \tilde{B} = \bigcup_{j=i}^{i+3} \lambda_j \) where \( \lambda_j \) lies on \( \tilde{S} \times \{j\} \). \( \pi_j \) denotes nearest-point projection of \( \tilde{S} \times \{j\} \) onto \( \lambda_j \) (in the appropriate sense - hyperbolic for \( j = i, i+3 \) and electric for \( j = i+1, i+2 \)). Next, since \( \phi \) is an electric isometry, but a hyperbolic quasi-isometry, there exists \( C > 0 \) (uniform constant) and \( K = K(B) \) such that for all \( (x, i) \in \lambda_i \), \( (\phi(x), i+1) \) lies in an (electric) \( C \)-neighborhood and a hyperbolic \( K \)-neighborhood of \( \Phi(\lambda_{i+1}) = \lambda_{i+2} \). The same holds for \( \phi^{-1} \) and points in \( \lambda_{i+2} \), where \( \phi^{-1} \) denotes the quasi-isometric inverse of \( \phi \) from \( \tilde{S} \times \{i+2\} \) to \( \tilde{S} \times \{i+1\} \).

Again, since \( \lambda_{i+1} \) and \( \lambda_{i+2} \) are electro-ambient quasigeodesics, we further note that there exists \( C > 0 \) (assuming the same \( C \) for convenience) such that for all \( (x, i) \in \lambda_i \), \( (x, i+1) \) lies in a (hyperbolic) \( C \)-neighborhood of \( \lambda_{i+1} \). Similarly for all \( (x, i+2) \in \lambda_{i+2} \), \( (x, i+3) \) lies in a (hyperbolic) \( C \)-neighborhood of \( \lambda_{i+3} \). The same holds if we go ‘down’ from \( \lambda_{i+1} \) to \( \lambda_i \) or from \( \lambda_{i+3} \) to \( \lambda_{i+2} \). The \( B_\lambda \)-elementary admissible paths in \( \tilde{B} \) consist of the following:

1) Horizontal subsegments of \( \lambda_j \), \( j = \{i, \cdots i+3\} \).
2) Vertical segments of length 1 joining \( x \times \{j\} \) to \( x \times \{j+1\} \), for \( j = i, i+2 \).
3) Horizontal geodesic segments lying in a hyperbolic \( C \)-neighborhood of \( \lambda_j \), \( j = i, \cdots i+3 \).
4) Horizontal hyperbolic segments of electric length \( \leq C \) and hyperbolic length
Definition: A $B_\lambda$-admissible path is a union of $B_\lambda$-elementary admissible paths.

The following lemma follows from the above definition and Lemma 5.5.

**Lemma 5.6.** There exists a function $g : \mathbb{Z} \to \mathbb{N}$ such that for any block $B_i$, and $x$ lying on a $B_\lambda$-admissible path in $\tilde{B}_i$, there exist $y \in \lambda_j$ and $z \in \lambda_k$ where $\lambda_j \subset B_\lambda$ and $\lambda_k \subset B_\lambda$ lie on the two boundary horizontal sheets, satisfying:

\[
d(x, y) \leq g(i)
\]

\[
d(x, z) \leq g(i)
\]

Let $h(i) = \Sigma_{j=0}^{i-1} g(j)$ be the sum of the values of $g(j)$ as $j$ ranges from 0 to $i$ (with the assumption that increments are by +1 for $i \geq 0$ and by −1 for $i \leq 0$). Then we have from Lemma 5.6 above.

**Corollary 5.7.** There exists a function $h : \mathbb{Z} \to \mathbb{N}$ such that for any block $B_i$, and $x$ lying on a $B_\lambda$-admissible path in $\tilde{B}_i$, there exist $y \in \lambda_0 = \lambda$ such that:

\[
d(x, y) \leq h(i)
\]

**Important Note:** In the above Lemma 5.6 and Corollary 5.7, it is important to note that the distance $d$ is *hyperbolic*, not electric. This is because the number $l_i$ occurring in elementary paths of type 5 and 6 is a hyperbolic length depending only on $i$ (in $B_i$).

Next suppose that $\lambda$ lies outside $B_N(p)$, the $N$-ball about a fixed reference point $p$ on the boundary horizontal surface $\tilde{S} \times \{0\} \subset \tilde{B}_0$. Then by Corollary 5.7, any $x$ lying on a $B_\lambda$-admissible path in $\tilde{B}_i$ satisfies

\[
d(x, p) \geq N - h(i)
\]

Also, since the electric, and hence hyperbolic ‘thickness’ (the shortest distance between its boundary horizontal sheets) is $\geq 1$, we get,

\[
d(x, p) \geq |i|
\]

Assume for convenience that $i \geq 0$ (a similar argument works, reversing signs for $i < 0$). Then,

\[
d(x, p) \geq min\{i, N - h(i)\}
\]

Let $h_1(i) = h(i) + i$. Then $h_1$ is a monotonically increasing function on the integers. If $h_1^{-1}(N)$ denote the largest positive integer $n$ such that $h(n) \leq m$, then clearly, $h_1^{-1}(N) \to \infty$ as $N \to \infty$. We have thus shown:

**Lemma 5.8.** There exists a function $M(N) : \mathbb{N} \to \mathbb{N}$ such that $M(N) \to \infty$ as $N \to \infty$ for which the following holds:

For any geodesic $\lambda \subset \tilde{S} \times \{0\} \subset \tilde{B}_0$, a fixed reference point $p \in \tilde{S} \times \{0\} \subset \tilde{B}_0$ and any $x$ on a $B_\lambda$-admissible path,

\[
d(\lambda, p) \geq N \Rightarrow d(x, p) \geq M(N).
\]

As pointed out before, the discussion and Lemmas of the previous two subsections go through just as well in the context of *weak amalgamation geometry* manifolds. We make this explicit in the case of Lemma 5.8 above.
Corollary 5.9. Let $M$ be a model manifold of weak amalgamation geometry. Then there exists a function $M(N) : \mathbb{N} \to \mathbb{N}$ such that $M(N) \to \infty$ as $N \to \infty$ for which the following holds:

Given any geodesic $\lambda \subset \tilde{S} \times \{0\}$, let $B_\lambda$ be as before. For $\lambda \subset \tilde{S} \times \{0\} \subset \tilde{B}_0$, a fixed reference point $p \in \tilde{S} \times \{0\} \subset \tilde{B}_0$ and any $x$ on a $B_\lambda$-admissible path,

$$d(\lambda, p) \geq N \Rightarrow d(x, p) \geq M(N).$$

5.4. Joining the Dots. Recall that admissible paths in a model manifold of bounded geometry consist of:

1) Horizontal segments along some $\tilde{S} \times \{i\}$ for $i = \{0, 1, 2, 3\}$ (thin blocks) or $i = \{0, 1\}$ (thick blocks).
2) Vertical segments $x \times [0, 1]$ or $x \times [2, 3]$ for amalgamated blocks.
3) Vertical segments of length $\leq l_i$ joining $x \times \{1\}$ to $x \times \{2\}$ for amalgamated blocks.
4) Vertical segments of length 1 joining $x \times \{0\}$ to $x \times \{1\}$ for thick blocks.

Our strategy in this subsection is:

- Start with an electric geodesic $\beta_e$ in $\tilde{M}_{\mathrm{Get}}$ joining the end-points of $\lambda$.
- Replace it by an admissible quasigeodesic, i.e., an admissible path that is a quasigeodesic.
- Project the intersection of the admissible quasigeodesic with the horizontal sheets onto $B_\lambda$.
- Join the dots using $B_\lambda$-admissible paths.

The end product is an electric quasigeodesic built up of $B_\lambda$ admissible paths.

Now for the first two steps:

- Since $\tilde{B}$ (for a thick block $B$) has thickness 1, any path lying in a thick block can be perturbed to an admissible path lying in $\tilde{B}$, changing the length by at most a bounded multiplicative factor.
- For $B$ amalgamated, we decompose paths into horizontal paths lying in some $\tilde{S} \times \{j\}$, for $j = 0, \cdots, 3$ and vertical paths of types (2) or (3) above. This can be done without altering electric length within $\tilde{S} \times [1, 2]$. To see this, project any path $\tilde{a}b$ beginning and ending on $\tilde{S} \times \{1, 2\}$ onto $\tilde{S} \times \{1\}$ along the fibers. To connect this to the starting and ending points $a, b$, we have to adjoin vertical segments through $a, b$. Note that this does not increase the electric length of $\tilde{a}b$, as the electric length is determined by the number of amalgamation blocks that $\tilde{a}b$ traverses.
- For paths lying in $\tilde{S} \times [0, 1]$ or $\tilde{S} \times [2, 3]$, we can modify the path into an admissible path, changing lengths by a bounded multiplicative constant. The result is therefore an electric quasigeodesic.
- Without loss of generality, we can assume that the electric quasigeodesic is one without back-tracking (as this can be done without increasing the length of the geodesic - see [Far98] or [Kla99] for instance).
- Abusing notation slightly, assume therefore that $\beta_e$ is an admissible electric quasi-geodesic without backtracking joining the end-points of $\lambda$.

This completes Steps $\bullet 1$ and $\bullet 2$. 
Now act on $\beta_c \cap \tilde{M}_H$ by $\pi_\lambda$. From Theorem 5.1, we conclude, by restricting $\pi_\lambda$ to the horizontal sheets of $\tilde{M}_G\tilde{e}$ that the image $\pi_\lambda(\beta_c)$ is a ‘dotted electric quasigeodesic’ lying entirely on $B_\lambda$. This completes step 3.

• Note that since $\beta_c$ consists of admissible segments, we can arrange so that two nearest points on $\beta_c \cap \tilde{M}_H$ which are not connected to each other form the endpoints of a vertical segment of type (2), (3) or (4). Let $\pi_\lambda(\beta_c) \cap B_\lambda = \beta_d$, be the dotted quasigeodesic lying on $B_\lambda$. We want to join the dots in $\beta_d$ converting it into a connected electric quasigeodesic built up of $B_\lambda$-admissible paths.

• For vertical segments of type (4) joining $p,q$ (say), $\pi_\lambda(p),\pi_\lambda(q)$ are a bounded hyperbolic distance apart. Hence, by the proof of Lemma 4.3, we can join $\pi_\lambda(p),\pi_\lambda(q)$ by a $B_\lambda$-admissible path of length bounded by some $C_0$ (independent of $B,\lambda$).

• For vertical segments of type (2) joining $p,q$, we note that $\pi_\lambda(p),\pi_\lambda(q)$ are a bounded hyperbolic distance apart. Hence, by the proof of Lemma 4.4, we can join $\pi_\lambda(p),\pi_\lambda(q)$ by a $B_\lambda$-admissible path of length bounded by some $C_1$ (independent of $B,\lambda$).

• This leaves us to deal with case (3). Such a segment consists of a segment lying within a lift of an amalgamation block. Such a piece has electric length one in the graph model. Its image, too, has electric length one (See for instance, Case (3) of the proof of Lemma 4.4, where we noted that the projection of any amalgamation component lies within an amalgamation component).

After joining the dots, we can assume further that the quasigeodesic thus obtained does not backtrack (cf [Far98] and [Kla99]).

Putting all this together, we conclude:

**Lemma 5.10.** There exists a function $M(N) : \mathbb{N} \to \mathbb{N}$ such that $M(N) \to \infty$ as $N \to \infty$ for which the following holds:

For any geodesic $\lambda \subset \tilde{S} \times \{0\} \subset \tilde{B}_0$, and a fixed reference point $p \in \tilde{S} \times \{0\} \subset \tilde{B}_0$, there exists a connected electric quasigeodesic $\beta_{adm}$ without backtracking, such that:

• $\beta_{adm}$ is built up of $B_\lambda$-admissible paths.
• $\beta_{adm}$ joins the end-points of $\lambda$.
• $d(\lambda,p) \geq N \Rightarrow d(\beta_{adm},p) \geq M(N)$.

**Proof:** The first two criteria follow from the discussion preceding this lemma. The last follows from Lemma 5.8 since the discussion above gives a quasigeodesic built up out of admissible paths. \(\square\)

As in the previous subsections, Lemma 5.10 goes through for weak amalgamation geometry. We state this below:

**Corollary 5.11.** Suppose that $M$ is a manifold of weak amalgamation geometry. There exists a function $M(N) : \mathbb{N} \to \mathbb{N}$ such that $M(N) \to \infty$ as $N \to \infty$ for which the following holds:

For any geodesic $\lambda \subset \tilde{S} \times \{0\} \subset \tilde{B}_0$, and a fixed reference point $p \in \tilde{S} \times \{0\} \subset \tilde{B}_0$, there exists a connected electric quasigeodesic $\beta_{adm}$ without backtracking, such that:

• $\beta_{adm}$ is built up of $B_\lambda$-admissible paths.
• $\beta_{adm}$ joins the end-points of $\lambda$.
• $d(\lambda,p) \geq N \Rightarrow d(\beta_{adm},p) \geq M(N)$.

5.5. Admissible Quasigeodesics and Electro-ambient Quasigeodesics. Definition: We next define (as before) a $(k,\epsilon)$ electro-ambient quasigeodesic $\gamma$ in $M$
relative to the amalgamation components $\tilde{K}$ to be a $(k, \epsilon)$ quasigeodesic in the graph model of $\tilde{M}$ such that in an ordering (from the left) of the amalgamation components that $\gamma$ meets, each $\gamma \cap \tilde{K}$ is a $(k, \epsilon)$-quasigeodesic in the induced path-metric on $\tilde{K}$.

This subsection is devoted to extracting an electro-ambient quasigeodesic $\beta_{ea}$ from a $B_{\lambda}$-admissible quasigeodesic $\beta_{adm}$. $\beta_{ea}$ shall satisfy the property indicated by Lemma 5.10 above. We shall prove this Lemma under the assumption of (strong) amalgamation geometry. However, a weaker assumption (which we shall discuss later, while weakening amalgamation geometry to graph amalgamation geometry) is enough for the main Lemma of this subsection to go through.

**Lemma 5.12.** There exist $\kappa, \epsilon$ and a function $M'(N) : \mathbb{N} \to \mathbb{N}$ such that $M'(N) \to \infty$ as $N \to \infty$ for which the following holds:

For any geodesic $\lambda \subset \tilde{S} \times \{0\} \subset \tilde{B}_0$, and a fixed reference point $p \in \tilde{S} \times \{0\} \subset \tilde{B}_0$, there exists a $(\kappa, \epsilon)$ electro-ambient quasigeodesic $\beta_{ea}$ without backtracking, such that

- $\beta_{ea}$ joins the end-points of $\lambda$.
- $d(\lambda, p) \geq N \Rightarrow d(\beta_{ea}, p) \geq M'(N)$.

**Proof:** From Lemma 5.10, we have a $B_{\lambda}$-admissible quasigeodesic $\beta_{adm}$ and a function $M(N)$ without backtracking satisfying the conclusions of the Lemma. Since $\beta_{adm}$ does not backtrack, we can decompose it as a union of non-overlapping segments $\beta_1, \ldots, \beta_k$, such that each $\beta_i$ is either an admissible (hyperbolic) quasigeodesic lying outside amalgamation components, or a $B_{\lambda}$-admissible quasigeodesic lying entirely within some amalgamation component $\tilde{K}_i$. Further, since $\beta_{adm}$ does not backtrack, we can assume that all $\tilde{K}_i$’s are distinct.

We modify $\beta_{adm}$ to an electro-ambient quasigeodesic $\beta_{ea}$ as follows:

1) $\beta_{ea}$ coincides with $\beta_{adm}$ outside amalgamation components.
2) There exist $\kappa, \epsilon$ such that if some $\beta_i$ lies within an amalgamation component $\tilde{K}_i$, then, by uniform quasiconvexity of the $\tilde{K}_i$’s, it may be replaced by a $(\kappa, \epsilon)$ (hyperbolic) quasigeodesic $\beta_{ea}^i$ joining the end-points of $\beta_i$ and lying within $\tilde{K}_i$.

The resultant path $\beta_{ea}$ is clearly an electro-ambient quasigeodesic without backtracking. Next, each component $\beta_{ea}^i$ lies in a $C_i$ neighborhood of $\beta_i$, where $C_i$ depends only on the thickness $l_i$ of the amalgamation component $\tilde{K}_i$.

We let $C(n)$ denote the maximum of the values of $C_i$ for $K_i \subset B_n$. Then, as in the proof of Lemma 5.8, we have for any $z \in \beta_{ea} \cap B_n$,

$$d(z, p) \geq \max (n, M(N) - C(n))$$

Again, as in Lemma 5.8, this gives us a (new) function $M'(N) : \mathbb{N} \to \mathbb{N}$ such that $M'(N) \to \infty$ as $N \to \infty$ for which

- $d(\lambda, p) \geq N \Rightarrow d(\beta_{ea}, p) \geq M'(N)$.

This proves the Lemma. $\square$

**Note:** We have essentially used the following two properties of amalgamation components in concluding Lemma 5.12:

1) any path lying inside an amalgamation component $\tilde{K}$ may be replaced by a (uniform) hyperbolic quasigeodesic joining its end-points and lying within
the same $\tilde{K}$

(2) Each electro-ambient quasigeodesic joining the end-points of an admissible quasigeodesic in $\tilde{K} \subset \tilde{B}_n$ lies in a (hyperbolic) $C(n)$-neighborhood of the latter.

We shall have occasion to use this when we discuss graph-quasiconvexity.

6. Cannon-Thurston Maps for Surfaces Without Punctures

It is now time to introduce hyperbolicity of $\tilde{M}$, global quasiconvexity of amalgamation components, (and hence) model manifolds of (strong) amalgamation geometry. We shall assume till the end of this section that
1) there exists a hyperbolic manifold $M$ and a homeomorphism from $\tilde{M}$ to $\tilde{S} \times \mathbb{R}$. We identify $\tilde{M}$ with $\tilde{S} \times \mathbb{R}$ via this homeomorphism.
2) $\tilde{S} \times \mathbb{R}$ admits a quasi-isometry $g$ to a model manifold of amalgamated geometry
3) $g$ preserves the fibers over $\mathbb{Z} \subset \mathbb{R}$

We shall henceforth ignore the quasi-isometry $g$ and think of $\tilde{M}$ itself as the universal cover of a model manifold of amalgamated geometry.

6.1. Electric Geometry Revisited. We note the following properties of the pair $(X, \mathcal{H})$ where $X$ is the graph model of $\tilde{M}$ and $\mathcal{H}$ consists of the amalgamation components. There exist $C, D, \Delta$ such that
1) Each amalgamation component is $C$-quasiconvex.
2) Any two amalgamation components are 1-separated.
3) $\tilde{M}_{Gel} = X_{Gel}$ is $\Delta$-hyperbolic, (where $\tilde{M}_{Gel} = X_{Gel}$ is the electric metric on $\tilde{M} = X$ obtained by electrocuting all amalgamation components, i.e. all members of $\mathcal{H}$).
4) Given $K, \epsilon$, there exists $D_0$ such that if $\gamma$ be a $(K, \epsilon)$ hyperbolic quasigeodesic joining $a, b$ and if $\beta$ be a $(K, \epsilon)$ electro-ambient quasigeodesic joining $a, b$, then $\gamma$ lies in a $D_0$ neighborhood of $\beta$.

The first property follows from the definition of a manifold of amalgamation geometry.
The second follows from the construction of the graph model.
The third follows from Lemma 3.3.
The fourth follows from Lemma 3.7.

6.2. Proof of Theorem. We shall now assemble the proof of the main Theorem.

Theorem 6.1. Let $M$ be a 3 manifold homeomorphic to $S \times J$ (for $J = [0, \infty)$ or $(-\infty, \infty)$). Further suppose that $M$ has amalgamated geometry, where $S_0 \subset B_0$ is the lower horizontal surface of the building block $B_0$. Then the inclusion $i : \tilde{S} \to \tilde{M}$ extends continuously to a map $\tilde{i} : \tilde{S} \to \tilde{M}$. Hence the limit set of $\tilde{S}$ is locally connected.

Proof: Suppose $\lambda \subset \tilde{S}$ lies outside a large $N$-ball about $p$. By Lemma 5.12 we obtain an electro-ambient quasigeodesic without backtracking $\beta_{ea}$ lying outside an $M(N)$-ball about $p$ (where $M(N) \to \infty$ as $N \to \infty$).

Suppose that $\beta_{ea}$ is a $(\kappa, \epsilon)$ electro-ambient quasigeodesic. Note that $\kappa, \epsilon$ depend on ‘the Lipschitz constant’ of $\Pi_\lambda$ and hence only on $\tilde{S}$ and $\tilde{M}$. 

From Property (4) above, (or Lemma 3.7) we find that if $\beta^h$ denote the hyperbolic geodesic in $\tilde{M}$ joining the end-points of $\lambda$, then $\beta^h$ lies in a (uniform) $C'$ neighborhood of $\beta_{ea}$.

Let $M_1(N) = M(N) - C'$. Then $M_1(N) \to \infty$ as $N \to \infty$. Further, the hyperbolic geodesic $\beta^h$ lies outside an $M_1(N)$-ball around $p$. Hence, by Lemma 2.3, the inclusion $i : \tilde{S} \to \tilde{M}$ extends continuously to a map $\hat{i} : \hat{S} \to \hat{M}$.

Since the continuous image of a compact locally connected set is locally connected (see [HY61]) and the (intrinsic) boundary of $\tilde{S}$ is a circle, we conclude that the limit set of $\tilde{S}$ is locally connected.

This proves the theorem. $\Box$

7. Weakening the Hypothesis I: Graph Quasiconvexity and Graph Amalgamation Geometry

We now proceed to weaken the hypothesis of amalgamation geometry in the hope of capturing all Kleinian surface groups. Recall that in the definition of amalgamation geometry, two criteria were used - local and global quasiconvexity of amalgamation components. We shall retain local quasiconvexity, and replace global quasiconvexity by a weaker condition which we shall term graph quasiconvexity. The rationale behind this terminology shall be made clear later. We first modify the definition of amalgamation geometry as follows, retaining only local quasiconvexity. We first recall the definition of weak amalgamation geometry.

A manifold $M$ homeomorphic to $S \times J$, where $J = [0, \infty)$ or $J = (-\infty, \infty)$, is said to be a model of weak amalgamation geometry if

1) there is a fiber preserving homeomorphism from $M$ to $\tilde{S} \times J$ that lifts to a quasi-isometry of universal covers.

2) there exists a sequence $I_i$ of intervals (with disjoint interiors) and blocks $B_i$ where the metric on $S \times I_i$ is the same as that on some building block $B_1$. Each block is either thick or has amalgamation geometry.

3) $\bigcup_i I_i = J$

4) There exists $C > 0$ such that for all amalgamated blocks $B_i$ and geometric cores $K \subset B_i$, all amalgamation components of $\tilde{K}$ are $C$-quasiconvex in $\tilde{B}_i$.

**Definition 7.1.** An amalgamation component $K \subset B_n$ is said to be $\text{(m, } \kappa \text{)}$ graph-quasiconvex if there exists a $\kappa$-quasiconvex (in the hyperbolic metric) subset $\text{CH}(K)$ containing $K$ such that

1) $\text{CH}(K) \subset N^G_m(K)$ where $N^G_m(K)$ denotes the $m$ neighborhood of $K$ in the graph model of $M$.

2) For each $K$ there exists $C_K$ such that $K$ is $C_K$-quasiconvex in $\text{CH}(K)$.

Since the quasiconvex sets (thought of as convex hulls of $K$) lie within a bounded distance from $K$ in the graph model we have used the term graph-quasiconvex.

**Definition 7.2.** A manifold $M$ of weak amalgamation geometry is said to be a model of graph amalgamation geometry if there exist $m, \kappa$ such that each amalgamation geometry component is $\text{(m, } \kappa \text{)}$-graph-quasiconvex.

A manifold $N$ is said to have graph amalgamation geometry if there is a level-preserving homeomorphism from $N$ to a model manifold of graph amalgamation geometry that lifts to a quasi-isometry at the level of universal covers.
Note: As before, we proceed with the assumption that for surfaces with punctures, \( S \) corresponds to a complete hyperbolic surface \( S^h \) minus a neighborhood of the cusps with horocycles electrocuted. Further, \( M \) corresponds to \( M^h \) minus a neighborhood of the cusps with resultant horospheres partially electrocuted.

Now, let us indicate the modifications necessary to carry out the proof of the Cannon-Thurston Property for manifolds of graph amalgamation geometry (suppressing the quasi-isometry to a model manifold). As in Theorem 6.1, the proof consists of two steps:
1) Constructing a quasiconvex set \( B_\lambda \) in an auxiliary electric space (the graph model), and from this an admissible electric quasigeodesic \( \beta \).
2) Recovering from \( \beta \) and its intersection pattern, information about the hyperbolic geodesic joining its end-points.

The first step is the same as that for models of amalgamation geometry as it goes through for weak amalgamation geometry. Then from Corollary 5.2 we have:

**Step 1A:** Given \( \lambda \subseteq \tilde{S} \times \{0\} \subseteq \tilde{M}_H \), construct \( B_\lambda, \Pi_\lambda \) as before. There exists \( C > 0 \) such that the retraction \( \Pi_\lambda : \tilde{M}_H \to B_\lambda \) satisfies:
\[
d_{Gel}(\Pi_\lambda(x), \Pi_\lambda(y)) \leq Cd_{Gel}(x,y) + C,
\]
where \( d_{Gel} \) denotes the metric in the graph model.

Again, from Corollary 5.11 we have:

**Step 1B:**
There exists a function \( M(N) : \mathbb{N} \to \mathbb{N} \) such that \( M(N) \to \infty \) as \( N \to \infty \) for which the following holds:
For any geodesic \( \lambda \subseteq \tilde{S} \times \{0\} \subseteq \tilde{B}_0 \), and a fixed reference point \( p \in \tilde{S} \times \{0\} \subseteq \tilde{B}_0 \), there exists a connected \( B_\lambda \)-admissible quasigeodesic \( \beta_{adm} \) without backtracking, such that
- \( \beta_{adm} \) is built up of \( B_\lambda \)-admissible paths.
- \( \beta_{adm} \) joins the end-points of \( \lambda \).
- \( d(\lambda, p) \geq N \Rightarrow d(\beta_{adm}, p) \geq M(N) \). (\( d \) is the ordinary, non-electric metric.)

**Summary of Step 2:**
Now we come to the second step: recovering a hyperbolic geodesic from an electric geodesic.

This step can be further subdivided into two parts. In the first part we construct a second auxiliary space \( M_2 \) by electrocuting the elements \( CH(K) \). We show that the spaces \( M_1 \) and \( M_2 \) are quasi-isometric. In fact we show that the identity map on the underlying subset is a quasi-isometry. This step requires only the first condition in the definition of graph quasiconvexity. The second stage extracts information about an electro-ambient quasi-geodesic in \( \tilde{M}_2 \) from an admissible path in \( \tilde{M}_1 \).
It is at this second stage that we require the second condition: (not necessarily uniform) quasi-convexity of amalgamation components.

We now furnish the details.

**Step 2A:**
Let \( M_1 \) denote \( M \) with the graph metric obtained by electrocuting amalgamation
components. Next, let $M_2$ denote $M$ with an electric metric obtained by electrocuting the family of sets $CH(K)$ (for amalgamation components $K$) appearing in the definition of graph amalgamation geometry.

**Lemma 7.3.** The identity map on the underlying set $M$ from $M_1$ to $M_2$ induces a quasi-isometry of universal covers $\tilde{M}_1$ and $\tilde{M}_2$.

**Proof:** Let $d_1, d_2$ denote the electric metrics on $\tilde{M}_1$ and $\tilde{M}_2$. Since $K \subset CH(K)$ for every amalgamation component, we have right off

$$d_1(x, y) \leq d_2(x, y)$$

To prove a reverse inequality with appropriate constants, it is enough to show that each set $CH(K)$ (of diameter one in $M_2$) has uniformly bounded diameter in $M_1$. To see this, note that by definition of graph-quasiconvexity, there exists $n$ such that for all $K$ and each point $a$ in $CH(K)$, there exists a point $b \in K$ with $d_1(x, y) \leq n$. Hence by the triangle inequality,

$$d_2(x, y) \leq 2n + 1$$

Therefore,

$$d_2(x, y) \leq (2n + 1)d_1(x, y)$$

This proves the Lemma. □

**Step 2B:**

Now let $\beta_{adm}$ denote an admissible $B_\lambda$ quasigeodesic in $\tilde{M}_1$, which does not backtrack relative to the amalgamation components. By Lemma 7.3 above, $\beta_{adm}$ is a quasigeodesic in $\tilde{M}_2$. As in Lemma 5.12, using the Note following it, we conclude:

There exists a $\kappa, \epsilon$-electro-ambient quasigeodesic $\beta_{ea}$ in $\tilde{M}_2$ (as opposed to $\tilde{M}_1$, which is what we needed in the amalgamation geometry case). (See Lemma 5.12.) Note that in $\tilde{M}_2$, we electrocute the lifts of the sets $CH(K)$ rather than $\tilde{K}$'s.

We thus obtain, as in Lemma 5.12 a function $M'(N) : N \to N$ such that $M'(N) \to \infty$ as $N \to \infty$ for which the following holds:

For any geodesic $\lambda \subset \tilde{S} \times \{0\} \subset \tilde{B}_0$, and a fixed reference point $p \in \tilde{S} \times \{0\} \subset \tilde{B}_0$, there exists a $(\kappa, \epsilon)$ electro-ambient quasigeodesic $\beta_{ea}$ without backtracking, such that

- $\beta_{ea}$ joins the end-points of $\lambda$.
- $d(\lambda, p) \geq N \Rightarrow d(\beta_{ea}, p) \geq M'(N)$.

Finally, as in the proof of Theorem 6.1, we use Lemma 3.7 to conclude that the hyperbolic geodesic in $\tilde{M}$ joining the end-points of $\lambda$ lies in a uniform hyperbolic neighborhood of $\beta_{ea}$. This gives us Theorem 6.1 with graph amalgamation geometry replacing amalgamation geometry.

**Theorem 7.4.** Let $M$ be a 3 manifold homeomorphic to $S \times J$ (for $J = [0, \infty)$ or $(-\infty, \infty)$). Further suppose that $M$ has graph amalgamation geometry, where $S_0 \subseteq B_0$ is the lower horizontal surface of the building block $B_0$. Then the inclusion $i : \tilde{S} \to \tilde{M}$ extends continuously to a map $\hat{i} : \hat{S} \to \hat{M}$. Hence the limit set of $\tilde{S}$ is locally connected.
8. WEAKENING THE HYPOTHESIS II: SPLIT GEOMETRY

In this section, we shall weaken the hypothesis of graph amalgamation geometry further to include the possibility of Margulis tubes cutting across the blocks $B_i$. But before we do this, let us indicate a straightforward generalization of amalgamation geometry or graph amalgamation geometry.

8.1. More Margulis Tubes in a Block. A straightforward generalization of Theorem 6.1 (or Theorem 7.4) is to the case where more than one Margulis tube is allowed per block $B$, and each of these tubes splits the block $B$ locally. On the surface $S$, this corresponds to a number of disjoint (uniformly) bounded length curves. As before we require that each amalgamation component be uniformly quasiconvex (or graph quasiconvex) in $\tilde{M}$ for the proof of Theorem 6.1 (or Theorem 7.4) to go through. See the figure below for a schematic rendering of the model block of amalgamation geometry.

![Building Block for Generalized Amalgamation Geometry](image)

8.2. Motivation for Split Geometry. So far, we have assumed that the boundaries of amalgamated geometry blocks or graph amalgamated geometry blocks are all of bounded geometry. This assumption needs to be relaxed to accommodate general surface Kleinian groups. Before we define the objects of interest, we shall first informally analyse what went into the construction of the hyperbolic ladder $B_{\lambda}$. We require:

1) Horizontal surfaces $S_i$, all abstractly homeomorphic to each other
2) A block decomposition $M = \bigcup B_i$, where $B_{i-1} \cap B_i = S_i$
3) Given a geodesic $\lambda_i \subset \tilde{S}_i$, we require a (uniformly) large-scale retract $\pi_i$ of $\tilde{S}_i$ onto $\lambda_i$ and a prescription to construct $\lambda_{i+1} \subset \tilde{S}_{i+1}$. Thus, starting with $\lambda_0 \subset \tilde{S}_0$, we first construct $\pi_0$ and then inductively construct the pairs $(\lambda_i, \pi_i)$.
4) Each block $B_i$ has an auxiliary metric or pseudometric which induces the given path metrics on $S_{i-1}, S_i$.

We want to relax the assumption that $S_i$’s have bounded geometry, while retaining the essential properties of bounded geometry. As elsewhere in this paper we invoke the following (uncomfortably dictatorial) policy that we have adopted:

**Policy:** Electrocute anything that gives trouble.

What this policy means is that whenever some construction possibly gives rise to non-uniformity of some parameter(s), locate the source of non-uniformity and electrocute it. Then, at the end of the game, re-instate the original geometry by using comparison properties between ordinary hyperbolic geometry and electric geometry.
Thus, each $S_i$ is now allowed to have a pseudometric where a finite number of disjoint, bounded length (uniformly, independent of $i$) collection of simple closed geodesics are electrocuted. Then, instead of geodesics $\lambda_i \subset \hat{S}_i$, we shall require the $\lambda_i$ to be only electro-ambient geodesics. This will allow us to go ahead with the construction of $B_\lambda$.

One further comment as to how this solves the problem. Let us fix a small (less than Margulis constant) $\epsilon_0$. Given any hyperbolic surface $S^h$, we can simply electrocute thin parts, i.e. tubular neighborhoods of short (less than $\epsilon_0$) geodesics with boundaries of length $\epsilon_0$. Alternately, we can first cut out the interiors of these thin parts. Next, corresponding to each Margulis annulus that has been cut out, glue the corresponding boundary components of length $\epsilon_0$ together, and then electrocute the resulting closed curves.

This construction is adapted to the construction of split level surfaces in Minsky [Min02], and Brock-Canary-Minsky [BCM04].

8.3. Definitions. Topologically, a split subsurface $S^s$ of a surface $S$ is a (possibly disconnected, proper) subsurface with boundary such that $S - S^s$ consists of a non-empty family of non-homotopic annuli, which in turn are not homotopic into the boundary of $S^s$.

Geometrically, we assume that $S$ is given some finite volume hyperbolic structure. A split subsurface $S^s$ of $S$ has bounded geometry, i.e.

1) each boundary component of $S^s$ is of length $\epsilon_0$, and is in fact a component of the boundary of $N_k(\gamma)$, where $\gamma$ is a hyperbolic geodesic on $S$, and $N_k(\gamma)$ denotes its $k$-neighborhood.

2) For any closed geodesic $\beta$ on $S$, either $\beta \subset S - S^s$, or, the length of any component of $\beta \cap (S - S^s)$ is greater than $\epsilon_0$.

Topologically, a split block $B^s \subset B = S \times I$ is a topological product $S^s \times I$ for some connected $S^s$. However, its upper and lower boundaries need not be $S^s \times 1$ and $S^s \times 0$. We only require that the upper and lower boundaries be split subsurfaces of $S^s$. This is to allow for Margulis tubes starting (or ending) within the split block. Such tubes would split one of the horizontal boundaries but not both. We shall call such tubes hanging tubes. See figure below:

![Figure 6: Split Block with hanging tubes](image)

Geometrically, we require that the metric on a split block induces a path metric on its upper and lower horizontal boundary components, which are subsurfaces
of $S^s \times \partial I$, such that each horizontal boundary component is a (geometric) split surface. Further, the metric on $B^s$ induces on each vertical boundary component of a Margulis tube $\partial S^s \times I$ the product metric. Each boundary component for Margulis tubes that ‘travel all the way from the lower to the upper boundary’ is an annulus of height equal to length of $I$. We demand further that hanging tubes have length uniformly bounded below by $\eta_0 > 0$. Further, each such annulus has cross-section a round circle of length $\epsilon_0$. This leaves us to decide the metric on lower and upper boundaries of hanging tubes. Such boundaries are declared to have a metric equal to that on $S^1 \times [-\eta, \eta]$, where $S^1$ is a round circle of length $\epsilon_0$ and $\eta$ is a sufficiently small number.

**Note:** In the above definition, we do not require that the upper (or lower) horizontal boundary of a split block $B^s$ be connected for a connected $B^s$. This happens due to the presence of hanging tubes.

We further require that the distance between horizontal boundary components is at least 1, i.e. for a component $R$ of $S^s$ $d(R \times 0, R \times 1) \geq 1$. We define the thickness of a split block to be the supremum of the lengths of $x \times I$ for $x \in S^s$ and demand that it be finite (which holds under all reasonable conditions, e.g. a smooth metric; however, since we shall have occasion to deal with possibly discontinuous pseudometrics, we make this explicit). We shall denote the thickness of a split block $B^s$ by $l_B$.

Each component of a split block shall be called a split component. We further require that the ‘vertical boundaries’ (corresponding to Euclidean annuli) of split components be uniformly (independent of choice of a block and a split component) quasiconvex in the corresponding split component.

Note that the boundary of each split block has an intrinsic metric that is flat and corresponds to a Euclidean torus.

A lift of a split block to the universal cover of the block $B = S \times I$ shall be termed a split component of $\tilde{B}$.

**Remark:** The notion of split components we deal with here is closely related to the notion of bands described by Bowditch in [Bow05a], [Bow05b] and also to the notion of scaffolds introduced by Brock, Canary and Minsky in [BCM04].

We define a welded split block to be a split block with identifications as follows: Components of $\partial S^s \times 0$ are glued together if and only if they correspond to the same geodesic in $S - S^s$. The same is done for components of $\partial S^s \times 1$. A simple closed curve that results from such an identification shall be called a weld curve. For hanging tubes, we also weld the boundary circles of their lower or upper boundaries by simply collapsing $S^1 \times [-\eta, \eta]$ to $S^1 \times \{0\}$.

This may be done topologically or geometrically while retaining Dehn twist information about the curves. To record information about the Dehn twists, we have to define (topologically) a map that takes the lower boundary of a welded split block to the upper boundary. We define a map that takes $x \times 0$ to $x \times 1$ for every point in $S^s$. This clearly induces a map from the lower boundary of a welded split block to its upper boundary. However, this is not enough to give a well-defined map on paths. To do this, we have to record twist information about weld curves. The way to do this is to define a map on transversals to weld curves. The map is defined on transversals by recording the number of times a transversal to a weld curve $\gamma \times 0$ twists around $\gamma \times 1$ on the upper boundary of the welded split block.
Let the metric product $S^1 \times [0,1]$ be called the \textbf{standard annulus} if each horizontal $S^1$ has length $\epsilon_0$. For hanging tubes the standard annulus will be taken to be $S^1 \times [0,1/2]$. 

Next, we require another pseudometric on $B$ which we shall term the \textbf{tube-electrocuted metric}. We first define a map from each boundary annulus $S^1 \times I$ (or $S^1 \times [0,1/2]$ for hanging annuli) to the corresponding standard annulus that is affine on the second factor and an isometry on the first. Now glue the mapping cylinder of this map to the boundary component. The resulting ‘split block’ has a number of standard annuli as its boundary components. Call the split block $B^s$ with the above mapping cylinders attached, the \textbf{stabilized split block} $B^{st}$.

Glue boundary components of $B^{st}$ corresponding to the same geodesic together to get the \textbf{tube electrocuted metric} on $B$ as follows. Suppose that two boundary components of $B^{st}$ correspond to the same geodesic $\gamma$. In this case, these boundary components are both of the form $S^1 \times I$ or $S^1 \times [0,1/2]$ where there is a projection onto the horizontal $S^1$ factor corresponding to $\gamma$. Let $S^1_l \times J$ and $S^1_r \times J$ denote these two boundary components (where $J$ denotes $I$ or $[0,1/2]$). Then each $S^1 \times \{x\}$ has length $\epsilon_0$. Glue $S^1_l \times J$ to $S^1_r \times J$ by the natural ‘identity map’. Finally, on each resulting $S^1 \times \{x\}$ put the zero metric. Thus the annulus $S^1 \times J$ obtained via this identification has the zero metric in the \textbf{horizontal direction} $S^1 \times \{x\}$ and the Euclidean metric in the \textbf{vertical direction} $J$. The resulting block will be called the \textbf{tube-electrocuted block} $B_{tel}$ and the pseudometric on it will be denoted as $d_{tel}$. Note that $B_{tel}$ is homeomorphic to $S \times I$. The operation of obtaining a \textbf{tube electrocuted block and metric} $(B_{tel}, d_{tel})$ from a split block $B^s$ shall be called \textbf{tube electrocution}.

Next, fix a hyperbolic structure on a Riemann surface $S$ and construct the metric product $S \times \mathbb{R}$. Fix further a positive real number $l_0$.

**Definition 8.1.** An annulus $A$ will be said to be \textbf{vertical} if it is of the form $\sigma \times J$ for $\sigma$ a geodesic of length less than $l_0$ on $S$ and $J = [a,b]$ a closed sub-interval of $\mathbb{R}$. $J$ will be called the \textbf{vertical interval} for the vertical annulus $A$. A disjoint collection of annuli is said to be a \textbf{vertical system} of annuli if each annulus in the collection is vertical.

The above definition is based on a definition due to Bowditch [Bow05a],[Bow05b].

Suppose now that $S \times \mathbb{R}$ is equipped with a vertical system $\mathcal{A}$ of annuli. We shall call $z \in \mathbb{R}$
1) a \textbf{beginning level} if $z$ is the lower bound of a vertical interval for some annulus $A \in \mathcal{A}$.
2) an \textbf{ending level} if $z$ is the lower bound of a vertical interval for some annulus $A \in \mathcal{A}$.
3) an \textbf{intermediate level} if $z$ is an interior point of a vertical interval for some annulus $A \in \mathcal{A}$.

In the figure below (where for convenience, all appropriate levels are marked with integers), 2, 5, 11 and 14 are \textbf{beginning levels}, 4, 7, 13 and 16 are \textbf{ending levels}, 3, 6, 9, 12 and 15 are \textbf{intermediate levels}. We shall also allow Dehn twists to occur...
while going along the annulus.

A slight modification of the vertical annulus structure will sometimes be useful. Replacing each geodesic $\gamma$ on $S$ by a neighborhood $N_{\epsilon}(\gamma)$ for sufficiently small $\epsilon$, we obtain a vertical Margulis tube structure after taking products with vertical intervals. The family of Margulis tubes shall be denoted by $T$ and the union of their interiors as $\text{Int}T$. The union of $\text{Int}T$ and its horizontal boundaries (corresponding to neighborhoods of geodesics $\gamma \subset S$) shall be denoted as $\text{Int}^+T$.

**Thick Block**

Fix constants $D, \epsilon$ and let $\mu = [p, q]$ be an $\epsilon$-thick Teichmuller geodesic of length less than $D$. $\mu$ is $\epsilon$-thick means that for any $x \in \mu$ and any closed geodesic $\eta$ in the hyperbolic surface $S_x$ over $x$, the length of $\eta$ is greater than $\epsilon$. Now let $B$ denote the universal curve over $\mu$ reparametrized such that the length of $\mu$ is covered in unit time. Thus $B = S \times [0, 1]$ topologically.

$B$ is given the path metric and is called a thick building block.

Note that after acting by an element of the mapping class group, we might as well assume that $\mu$ lies in some given compact region of Teichmuller space. This is because the marking on $S \times \{0\}$ is not important, but rather its position relative to $S \times \{1\}$. Further, since we shall be constructing models only upto quasi-isometry, we might as well assume that $S \times \{0\}$ and $S \times \{1\}$ lie in the orbit under the mapping class group of some fixed base surface. Hence $\mu$ can be further simplified to be a Teichmuller geodesic joining a pair $(p, q)$ amongst a finite set of points in the orbit of a fixed hyperbolic surface $S$.

**Weak Split Geometry**

A manifold $S \times \mathbb{R}$ equipped with a vertical Margulis tube structure is said to be a model of weak split geometry, if it is equipped with a new metric satisfying the following conditions:

1) $S \times [m, m+1] \cap \text{Int}T = \emptyset$ (for $m \in \mathbb{Z} \subset \mathbb{R}$) implies that $S \times [m, m+1]$ is a thick block.

2) $S \times [m, m+1] \cap \text{Int}T \neq \emptyset$ (for $m \in \mathbb{Z} \subset \mathbb{R}$) implies that $S \times [m, m+1] - \text{Int}^+T$ is (geometrically) a split block.

3) There exists a uniform upper bound on the lengths of vertical intervals for vertical Margulis tubes.

4) The metric on each component Margulis tube $T$ of $\mathcal{T}$ is hyperbolic.
Note 1: Dehn twist information can still be implicitly recorded in a model of weak split geometry by the Dehn filling information corresponding to tubes $T$.

Note 2: The metric on a model of weak split geometry is possibly discontinuous along the boundary tori of Margulis tubes. If necessary, one could smooth this out. But we would like to carry on with the above metric.

Removing the interiors of Margulis tubes and tube electrocuting each block, we obtain a new pseudo-metric on $M$ called the tube electrocuted metric $d_{tel}$ on $M$. The pseudometric $d_{tel}$ may also be lifted to $\tilde{M}$.

The induced pseudometric on $\tilde{S}_i$’s shall be referred to as split electric metrics. The notions of electro-ambient metrics, geodesics and quasigeodesics go through in this context.

Next, we shall describe a graph metric on $\tilde{M}$ which is almost (but not quite) the metric on the nerve of the covering of $\tilde{M}$ by split components (where each edge is assigned length 1). This is not strictly true as thick blocks are retained with their usual geometry in the graph metric. However the analogy with the nerve is exact if all blocks have weak split geometry.

For each split component $\tilde{K}$ assign a single vertex $v_K$ and construct a cone of height $1/2$ with base $\tilde{K}$ and vertex $v_K$. The metric on the resulting space (coned-off or electric space in the sense of Farb [Far98]) shall be called the graph metric on $\tilde{M}$.

The union of a split component of $\tilde{B}$ and the lifts of Margulis tubes (to $\tilde{M}$) that intersect its boundary shall be called a split amalgamation component in $\tilde{M}$.

Definition 8.2. A split amalgamation component $K$ is said to be $(m, \kappa)$–graph quasiconvex if there exists a $\kappa$-quasiconvex (in the hyperbolic metric) subset $CH(K)$ containing $K$ such that

1. $CH(K) \subset N^G_m(K)$ where $N^G_m(K)$ denotes the $m$ neighborhood of $K$ in the graph metric on $\tilde{M}$.

2. For each $K$ there exists $C_K$ such that $K$ is $C_K$-quasiconvex in $CH(K)$.

A model manifold $M$ of weak split geometry is said to be a model of split geometry if there exist $m, \kappa$ such that each split amalgamation component is $(m, \kappa)$-graph quasiconvex.

8.4. The Cannon-Thurston Property for Manifolds of Split Geometry.
We shall first extract information about geodesics in the tube electrocuted model. As with Theorem 6.1 and Theorem 7.4, the proof splits into two parts:
Step 1: Construction of $B_\lambda$ and its quasiconvexity in an auxiliary graph metric. The end-product of this step is an electro-ambient quasigeodesic in the graph model
Step 2: Extraction of information about a hyperbolic geodesic and its intersection pattern with blocks from the electro-ambient quasigeodesic constructed in Step 1 above.

Details of Step 1:
Step 1A: Construction of $B_\lambda$
It is at this stage that the construction differs somewhat from the construction of $B_\lambda$ for manifolds of graph amalgamated geometry.
We start with the (tube-electrocuted) metric $d_{tel}$ on the model manifold of split geometry. Then there exists a sequence of split surfaces $\tilde{S}_i$ exiting the ends.

Recall that in the construction of $B_\lambda$ (for all preceding cases) we are not interested in the metric on each $\tilde{S}_i$ per se, but in geodesics on $\tilde{S}_i$.

The metric $d_{tel}$ on the model manifold induces the split electric metric on each $S_i$ obtained by electrocuting the weld curves. The natural geodesics to consider on $\tilde{S}_i$ are therefore the electro-ambient quasigeodesics where the electrocuted subsets correspond to geodesics representing the weld curves.

Thus we start off with a hyperbolic geodesic $\lambda$ in $\tilde{S}_0$ joining $a, b$ say. We let $\lambda_0$ denote the electro-ambient quasigeodesic joining $a, b$ in the split electric metric on $\tilde{S}_0$. Now construct $B_\lambda$ inductively as follows:

- Each split block $B_i$ and hence $\tilde{B}_i$ comes equipped with a (topological) product structure. Thus there is a canonical map $\Phi_i : \tilde{S}_i \to \tilde{S}_{i+1}$ which maps each $(x, i)$ to a point $(x, i + 1)$ by lifting the map from $S_i$ to $S_{i+1}$ ($i \geq 0$ corresponding to the product structure).
- Next, if $\lambda_i$ is an electro-ambient quasi-geodesic in the split electric metric on $\tilde{S}_i$ joining $(a, i)$ and $(b, i)$ we let $\lambda_{i+1}$ denote the electro-ambient quasigeodesic in the split-electric metric on $\tilde{S}_{i+1}$ joining $(a, i + 1)$ and $(b, i + 1)$. This gives us a prescription for constructing $\lambda_{i+1}$ from $\lambda_i$ for $i \geq 0$. Similarly, for $i \leq 0$ (in the totally degenerate case) we can construct $\lambda_{i-1}$ from $\lambda_i$. Then as before, define

$$B_\lambda = \bigcup_i \lambda_i$$

- Again, $\pi_i : \tilde{S}_i \to \lambda_i$ is defined as the retraction that minimizes the ordered pair of distances in the split electric metric and the hyperbolic metric (without electrocuting weld curves). $\Pi_\lambda$ is obtained in the graph metric by defining it on the horizontal sheets $\tilde{S}_i$ as

$$\Pi_\lambda(x) = \pi_i(x) \text{ for } x \in \tilde{S}_i.$$ 

- Then as before we conclude that in the graph model for $\tilde{M}$, with the metric $d_{Gel}$, $\Pi_\lambda$ does not stretch distances much, i.e. there exists a uniform $C \geq 0$ such that

$$d_{Gel}(\Pi_\lambda(x), \Pi_\lambda(y)) \leq Cd_{Gel}(x, y) + C$$

**Step 1B: Construction of admissible quasigeodesic**

The above construction of $\Pi_\lambda$ may be used to construct a $B_\lambda$-admissible quasigeodesic $\beta_{adm}$ in the tube-electrocuted model. As before we have:

There exists a function $M(N) : \mathbb{N} \to \mathbb{N}$ such that $M(N) \to \infty$ as $N \to \infty$ for which the following holds:

For any geodesic $\lambda \subset \tilde{S} \times \{0\} \subset \tilde{B}_0$, and a fixed reference point $p \in \tilde{S} \times \{0\} \subset \tilde{B}_0$, there exists a connected $B_\lambda$-admissible quasigeodesic $\beta_{adm}$ without backtracking, such that

- $\beta_{adm}$ is built up of $B_\lambda$-admissible paths.
- $\beta_{adm}$ joins the end-points of $\lambda$.
- If $d(\lambda, p) \geq N$ then for any $x \in \beta_{adm} - \text{Int} T$, $d(x, p) \geq M(N)$. ($d$ is the ordinary, hyperbolic, or non-electric metric.)
Step 2: Recovering a quasigeodesic in the tube electrocuted model from an admissible quasigeodesic

We now follow the proof of Theorem 7.4.

**Step 2A:** As in Step 2A in the proof of Theorem 7.4 we construct a second auxiliary space $M_2$ by electrocuting the elements $CH(K)$ for split components $K$. The spaces $\tilde{M}_1$ and $M_2$ are quasi-isometric by uniform graph quasiconvexity of split components. In fact the identity map on the underlying subset is a quasi-isometry as in Lemma 7.3.

**Step 2B** Next, as in Step 2B in the proof of Theorem 7.4, we extract information about an electro-ambient quasi-geodesic in $\tilde{M}_2$ from an admissible path in $\tilde{M}_1$. It is at this second stage that we require the condition that split components are (not necessarily uniformly) quasi-convex in the hyperbolic metric, and hence in the tube electrocuted metric $d_{tel}$.

We may assume that $\beta_{adm}$ does not backtrack relative to the split components. From Step 2A above, $\beta_{adm}$ is a quasigeodesic in $\tilde{M}_2$. Then we conclude:

There exists a $\kappa, \epsilon$-electro-ambient quasigeodesic $\beta_{tea}$ in $\tilde{M}_2$ (Note that in $\tilde{M}_2$, we electrocute the lifts of the sets $CH(K)$ rather than $\tilde{K}$’s).

We finally obtain a function $M'(N) : N \to \mathbb{N}$ such that $M'(N) \to \infty$ as $N \to \infty$ for which the following holds:

- For any geodesic $\lambda \subset \tilde{S} \times \{0\} \subset \tilde{B}_0$, and a fixed reference point $p \in \tilde{S} \times \{0\} \subset \tilde{B}_0$, there exists a $(\kappa, \epsilon)$ electro-ambient quasigeodesic $\beta_{tea}$ (in the tube electrocuted metric) without backtracking, such that
  - $\beta_{tea}$ joins the end-points of $\lambda$.
  - If $\lambda$ lies outside a large ball about a fixed reference point $p \in \tilde{S}_0$, then each point of $\beta_{tea} \cap (\tilde{M} - IntT)$ also lies outside a large ball about $p$.

**Step 3:** Recovering a hyperbolic geodesic from the tube electrocuted quasigeodesic $\beta_{tea}$

This is a new step that comes from the extra phenomenon of tube electrocution which makes the metric $d_{tel}$ an ‘intermediate’ metric between the hyperbolic metric $d$ and the graph metric $d_{Gel}$.

Observe that lifts of Margulis tubes to $(\tilde{M}, d_{Gel})$ have uniformly bounded diameter in the metric $d_{Gel}$ and consequently in the metric $d_{tel}$ by uniform boundedness of vertical intervals of vertical Margulis tubes. Hence the tube electrocuted metric $d_{tel}$ on $\tilde{M}$ is quasi-isometric to the metric $d_{fe}$ where lifts of Margulis tubes are electrocuted (i.e. fully electrocuted rather than just tube electrocuted, and hence each tube has diameter 1). Let $\tilde{M}_{fe}$ denote $\tilde{M}$ equipped with this new metric. Then geodesics without backtracking in the tube electrocuted metric become (uniform) quasi-geodesics without backtracking in $\tilde{M}_{fe}$.

**Note:** It is at this (rather late) stage that we need to assume that $\tilde{M}$ is a hyperbolic metric space.

Let $\gamma^h$ denote a hyperbolic geodesic joining the end-points of $\beta_{tea}$ and hence $\lambda$. By Lemma 3.15, $\gamma^h$ and $\beta_{tea}$ track each other off Margulis tubes. Hence $\gamma^h \cap (\tilde{M} - IntT)$ lies outside a large ball about $p$. In particular, this is true for entry and exit points of $\gamma^h$ with respect to Margulis tubes. This implies (See for instance Lemma 7.3 of [Mj05b] ) that the parts of $\lambda^h$ lying within Margulis tubes also lie
outside large balls about p. As before, by Lemma 2.3 we infer the Cannon-Thurston property for manifolds of split geometry.

**Theorem 8.3.** Let $M$ be a 3 manifold homeomorphic to $S \times J$ (for $J = [0, \infty)$ or $(-\infty, \infty)$). Further suppose that $M$ has split geometry, where $S_0 \subset B_0$ is the lower horizontal surface of the building block $B_0$. Then the inclusion $i : \tilde{S} \to \tilde{M}$ extends continuously to a map $\hat{i} : \hat{\tilde{S}} \to \hat{\tilde{M}}$. Hence the limit set of $\tilde{S}$ is locally connected.
