Abstract

The notion of \textit{i-bounded geometry} generalises simultaneously \textit{bounded geometry} and the geometry of punctured torus Kleinian groups. We show that the limit set of a surface Kleinian group of i-bounded geometry is locally connected by constructing a natural Cannon-Thurston map. This gives a unification, an alternate proof and a generalisation of all known examples of the existence of Cannon-Thurston maps for manifolds whose boundary is incompressible away from cusps. More specifically, it includes the results for manifolds of bounded geometry with or without punctures, (due to Cannon and Thurston, Minsky, Klarreich, Bowditch and the author), as also the result of McMullen for punctured torus groups.

8 Cannon-Thurston Maps for Pared Manifolds 51

1 Introduction

1.1 Statement of Results

This is the third in a series of papers (after [23] and [24]) dealing with
Cannon-Thurston maps and local connectivity of limit sets of Kleinian groups.
The main theorem of this paper is:

Theorem 8.1: Suppose that $N^h \in H(M, P)$ is a hyperbolic structure of i-bounded geometry on a pared manifold $(M, P)$ with incompressible boundary $\partial_0 M = (\partial M - P)$ (i.e. each component of $\partial_0 M$ is incompressible). Let $M_{gf}$ denotes a geometrically finite hyperbolic structure adapted to
Then the map \( \hat{i} : \hat{M}_{gf} \to \hat{N}^h \) extends continuously to the boundary \( \hat{\hat{i}} : \hat{M}_{gf} \to \hat{N}^h \). If \( \Lambda \) denotes the limit set of \( M \), then \( \Lambda \) is locally connected.

The notion of \textit{i-bounded geometry} generalises simultaneously \textit{bounded geometry} and the geometry of punctured torus Kleinian groups. In particular, since punctured torus groups have \textit{i-bounded geometry} by a result of Minsky [18], we have a new proof of the following Theorem of McMullen [16] as a consequence:

\textbf{Theorem 8.2} : (McMullen [16]) Let \( M^h \) be a hyperbolic 3 manifold homeomorphic to \( S^h \times J \) (for \( J = [0, \infty) \) or \( (-\infty, \infty) \)), where \( S^h \) is a punctured torus. Let \( i : S^h \to M^h \) be a type-preserving (i.e. taking parabolics to parabolics) homotopy equivalence. Then the inclusion \( \hat{i} : \hat{S}^h \to \hat{M}^h \) extends continuously to a map \( \hat{i} : \hat{S}^h \to \hat{M}^h \). Hence the limit set of \( S^h \) is locally connected.

\( i \)-\textit{bounded geometry} can roughly be described as bounded geometry away from Margulis tubes. But this description is a little ambiguous. More precisely, we start with a collection of (uniformly) bounded geometry blocks \( S \times I \) glued end to end. Next, for some blocks a curve is selected such that its representative on the lower end of the block has (uniformly) bounded length. Hyperbolic Dehn surgery is then performed along the geodesic representative within the block. Precise definitions will be given in Section 2.2.

We describe below a collection of examples of manifolds of \( i \)-\textit{bounded geometry} for which Theorem 8.1 is known:

1. The cover corresponding to the fiber subgroup of a closed hyperbolic 3-manifold fibering over the circle (Cannon and Thurston [6]).

2. Hyperbolic 3 manifolds of bounded geometry, which correspond to simply or doubly degenerate Kleinian groups isomorphic to closed surface groups (Minsky [17]).

3. Hyperbolic 3 manifolds of bounded geometry without parabolics and freely indecomposable fundamental group (Mitra - Section 4.3 of [23], and Klarreich [13]).
4. Hyperbolic 3 manifolds of bounded geometry, arising from simply or doubly degenerate Kleinian groups corresponding to punctured surface groups (Bowditch [3]).

5. Hyperbolic 3 manifolds of bounded geometry (possibly) with parabolics which arise from 3-manifolds whose boundary is incompressible away from cusps [24].

6. Punctured torus Kleinian groups (McMullen [16]).

Thus Theorem 8.1 gives a unification and strict generalisation of all known examples of the existence of Cannon-Thurston maps for manifolds whose boundary is incompressible away from cusps. More specifically, it includes the results for manifolds of bounded geometry with or without punctures, [6], [17], [13], [23], [3], [4], [24] as also the result of McMullen [16] for punctured torus groups.

In Section 4.3 of [23], the first paper of the present series, we showed that Cannon-Thurston maps exist for 3 manifolds of bounded geometry without parabolics and freely indecomposable fundamental group. This was directly motivated by Cannon and Thurston’s pioneering preprint [6]. The Cannon-Thurston result is really a theorem about maps on the boundary and hence should not, in principle, require local information (e.g. singular metrics arising from foliations as in the original proof in [6]). Thus an alternate approach (purely in terms of coarse geometry ignoring all local information) was given in [23]. The proof was general enough to include and generalise Minsky’s result for bounded geometry 3-manifolds [17]. A different approach was given by Klarreich [13], which uses Minsky’s result in an essential way. Klarreich’s result may well be thought of as a reduction theorem. What it essentially does is prove that existence of Cannon-Thurston maps for closed surface groups of bounded geometry implies the existence of Cannon-Thurston maps for bounded geometry 3 manifolds with freely indecomposable fundamental group.

The second paper of the present series [24] was motivated by Bowditch’s result [3] [4] for punctured surface Kleinian groups of bounded geometry. His proof uses some of the ideas of [23] but seems to depend on the special nature of punctured surfaces and Farey graphs, and hence does not appear to readily generalise and include surfaces without punctures. A different approach was
given in [24] generalising the approach of the first paper of the series [23]. The method is in certain ways simpler and has the advantage of including all 3 manifolds of bounded geometry whose cores are incompressible away from cusps. This is a strict generalisation of both Bowditch's result [3] as well as [23]. The proof has the advantage that it reduces to a proof for manifolds without punctures when the surface in question is closed. We also include at the start of the paper [24] (for motivation) the special case of surface Kleinian groups, where the proof is considerably simpler than that given by Bowditch [3].

The present paper (the third in the series) was motivated by McMullen's result [16] for punctured torus groups based on Minsky's model for these [18]. However, it seems difficult to directly generalise McMullen's techniques to higher genus surfaces (using singular foliations instead of ordinary foliations). In this paper we isolate a large-scale or coarse geometric feature involved in Minsky's model (which we call i-bounded geometry) and give a proof of the Cannon-Thurston property for model geometries of i-bounded geometry. In combination with the methods of [24] this is enough to bring under the same umbrella all known results on Cannon-Thurston maps for 3 manifolds that are incompressible away from cusps (or, pared manifolds $(M, P)$ with incompressible boundary as they are called in [24]). When $(M, P)$ is the pair $(S \times I, \delta S \times I)$, for $S$ a punctured torus or four-holed sphere, we get McMullen's result [16].

In a subsequent paper [25], we shall extend the notion of i-bounded geometry step-by-step to include more general situations.

This seems quite in keeping with the scheme of the proof of the Ending Lamination Conjecture, due to Minsky with major contributions by Masur, Brock and Canary [17], [18], [14], [15], [20], [5]. The first step was to prove the ELC for bounded geometry [17], then the punctured torus [18], and finally the general case [20] [5]. The present paper completes what may be thought of as the second stage in the corresponding proof of the existence of Cannon-Thurston maps.

Since the proof of the Ending Lamination Conjecture for the punctured torus groups can be likened to the first inductive step (and the case of bounded geometry to the zeroth inductive step) in the proof of the full Ending Lamination Conjecture, it seems quite natural that a proof of the corresponding conjecture (see for instance McMullen [16], or the author's doctoral thesis [21], [1]) for Cannon-Thurston maps and local connectivity of limit sets should follow a similar scheme. Our approach to this problem in [23]
and [24] can similarly be thought of as the zeroth inductive step and the present paper as the first inductive step.

We hasten to add that the ideas in the proof of our main Theorem 8.1 are independent of those in the proof of the Ending Lamination Conjecture. It is only when we want to say that certain 3-manifolds have i-bounded geometry (e.g. those corresponding to punctured torus groups) that we quote Minsky’s result.

The papers [22], [23] and [24] as well as the current one circumvent much of the sophisticated machinery specific to 2- and 3- manifolds developed by Thurston et al. Thus, they provide a direct approach to the existence of a Cannon-Thurston map, (as also local connectivity), without having to deal with laminations and associated geometries. The large-scale or coarse nature of our approach makes it more general, and suitable for application to cases where the surface machinery of Thurston is not available, e.g. general hyperbolic or relatively hyperbolic spaces and groups in the sense of Gromov. In the series of papers mentioned above, the place where we use the Thurston machinery is to prove that hyperbolic 3-manifolds do satisfy the conditions (e.g. i-bounded geometry) we impose on a manifold for the existence of a Cannon-Thurston map. This brings up the possibility of an axiomatisation of a sufficient set of conditions that need to be satisfied for the existence of a Cannon-Thurston map. We hope to deal with this in a future work.

1.2 Cannon-Thurston Maps and i-bounded geometry

Let \( S \) be a hyperbolic surface of finite area and let \( \rho(\pi_1(S)) = H \subset PSL_2(\mathbb{C}) \) be a representation, such that the quotient hyperbolic 3-manifold \( M = \mathbb{H}^3 / H \) is simply degenerate. Let \( \hat{S} \) and \( M \) denote the universal covers of \( S \) and \( M \) respectively. Then \( \hat{S} \) and \( M \) can be identified with \( \mathbb{H}^2 \) and \( \mathbb{H}^3 \) respectively. There exists a natural inclusion \( \hat{i} : \hat{S} \rightarrow M \). Now let \( \mathbb{D}^2 = \mathbb{H}^2 \cup S^1_{\infty} \) and \( \mathbb{D}^3 = \mathbb{H}^3 \cup S^2_{\infty} \) denote the standard compactifications. The local connectivity of the limit set of \( \hat{S} \) is equivalent to the existence of a continuous extension (a Cannon-Thurston map) \( \hat{i} : \mathbb{D}^2 \rightarrow \mathbb{D}^3 \).

However, for general (not necessarily surface) Kleinian groups, local connectivity follows from the existence of a Cannon-Thurston map and local connectivity of an isomorphic geometrically finite Kleinian group.

A word about the term i-bounded geometry. In [14] and [15], Masur and Minsky construct a hierarchy of what they call ‘tight geodesics’ in the curve-complex of a surface after having proven the hyperbolicity of the curve complex. A related result was proven by Minsky in [19].
In the construction of a general model manifold (Section 9 of [20]), as a step towards the resolution of the Ending Lamination Conjecture, Minsky describes certain (complex) meridian coefficients which encode the complex structure for boundary torii of Margulis tubes. The uniform boundedness of these coefficients corresponds to bounded geometry. The manifolds that we discuss in this paper correspond to those which have a uniform bound on the imaginary part of these coefficients. Hence the term i-bounded geometry. Clearly, manifolds of bounded geometry should have i-bounded geometry, as indeed they do. In [18], Minsky further showed that punctured torus groups (and four-holed sphere groups) have i-bounded geometry. Roughly speaking, the number of twists gives the real part and the number of vertical annuli gives the imaginary part of the coefficients. Hence, in a manifold of i-bounded geometry, an arbitrarily large number of twists are allowed for each Margulis tube, but only a uniformly bounded number of vertical annuli.

1.3 Outline of the paper

A brief outline of the paper follows. Section 2 deals with preliminaries. We also define i-bounded geometry via the construction of a model manifold.

Section 3 deals with relative hyperbolicity a la Gromov [10], Farb [8] and Bowditch [2].

As in [22], [23] and [24], our proof proceeds by constructing a ladder-like set $B_{\lambda} \subset M$ from a geodesic segment $\lambda \subset \tilde{S}$ and then a retraction $\Pi_{\lambda}$ of $M$ onto $B_{\lambda}$. We modify this construction in this paper and restrict our attention to one block, i.e. a copy of $\tilde{S} \times I$ minus certain neighborhoods of geodesics and cusps and equip it with a model pseudometric which is zero along lifts of a simple closed geodesic.

In Section 4, we construct a model geometry for the universal covers of building blocks and the relevant geometries (electric and graph models) that will concern us.

We also construct the paths that go to build up the ladder-like set $B_{\lambda}$. We further construct the restriction of the retraction $\Pi_{\lambda}$ to this block and show that it does not increase distances much.

To prevent cluttering, we restrict ourselves to closed surfaces first, and then indicate the modifications necessary for punctured surfaces.

In Section 5, we put the blocks and retractions together (by adding them one on top of another) to build the ladder-like $B_{\lambda}$ and prove the main technical theorem - the existence of of a retract $\Pi_{\lambda}$ of $\tilde{M}$ onto $B_{\lambda}$. This shows that $B_{\lambda}$ is quasiconvex in $M$ equipped with a model pseudometric.

7
In Section 6, we put together the ingredients from Sections 2, 3, 4 and 5 to prove the existence of a Cannon-Thurston map for simply or doubly degenerate Kleinian groups corresponding to representations of closed surface groups, such that the resulting manifold has $i$-bounded geometry.

In Section 7, we generalise the result of Section 6 to surfaces with punctures.

In Section 8, we combine the results of Sections 6 and 7 with the techniques of [24] to prove the main theorem of the paper.

2 Preliminaries

2.1 Hyperbolic Metric Spaces

We start off with some preliminaries about hyperbolic metric spaces in the sense of Gromov [10]. For details, see [7], [9]. Let $(X,d)$ be a hyperbolic metric space. The Gromov boundary of $X$, denoted by $\partial X$, is the collection of equivalence classes of geodesic rays $r : [0, \infty) \to \Gamma$ with $r(0) = x_0$ for some fixed $x_0 \in X$, where rays $r_1$ and $r_2$ are equivalent if $\sup\{d(r_1(t), r_2(t))\} < \infty$. Let $\widehat{X} = X \cup \partial X$ denote the natural compactification of $X$ topologized the usual way(cf.[9] pg. 124).

The Gromov inner product of elements $a$ and $b$ relative to $c$ is defined by

$$(a,b)_c = \frac{1}{2}[d(a,c) + d(b,c) - d(a,b)].$$

Definitions: A subset $Z$ of $X$ is said to be $k$-quasiconvex if any geodesic joining points of $Z$ lies in a $k$-neighborhood of $Z$. A subset $Z$ is quasiconvex if it is $k$-quasiconvex for some $k$. (For simply connected real hyperbolic manifolds this is equivalent to saying that the convex hull of the set $Z$ lies in a bounded neighborhood of $Z$. We shall have occasion to use this alternate characterisation.) A map $f$ from one metric space $(Y,d_Y)$ into another metric space $(Z,d_Z)$ is said to be a $(K,\epsilon)$-quasi-isometric embedding if

$$\frac{1}{K}(d_Y(y_1,y_2)) - \epsilon \leq d_Z(f(y_1), f(y_2)) \leq K d_Y(y_1,y_2) + \epsilon$$

If $f$ is a quasi-isometric embedding, and every point of $Z$ lies at a uniformly bounded distance from some $f(y)$ then $f$ is said to be a quasi-isometry. A $(K,\epsilon)$-quasi-isometric embedding that is a quasi-isometry will be called a $(K,\epsilon)$-quasi-isometry.
A \((K, \epsilon)\)-quasigeodesic is a \((K, \epsilon)\)-quasi-isometric embedding of a closed interval in \(\mathbb{R}\). A \((K, K)\)-quasigeodesic will also be called a \(K\)-quasigeodesic.

Let \((X, d_X)\) be a hyperbolic metric space and \(Y\) be a subspace that is hyperbolic with the inherited path metric \(d_Y\). By adjoining the Gromov boundaries \(\partial X\) and \(\partial Y\) to \(X\) and \(Y\), one obtains their compactifications \(\tilde{X}\) and \(\tilde{Y}\) respectively.

Let \(i : Y \to X\) denote inclusion.

**Definition:** Let \(X\) and \(Y\) be hyperbolic metric spaces and \(i : Y \to X\) be an embedding. A **Cannon-Thurston map** \(\hat{i}\) from \(\tilde{Y}\) to \(\tilde{X}\) is a continuous extension of \(i\).

The following lemma (Lemma 2.1 of [22]) says that a Cannon-Thurston map exists if for all \(M > 0\) and \(y \in Y\), there exists \(N > 0\) such that if \(\lambda\) lies outside an \(N\)-ball around \(y\) in \(Y\) then any geodesic in \(X\) joining the end-points of \(\lambda\) lies outside the \(M\)-ball around \(i(y)\) in \(X\). For convenience of use later on, we state this somewhat differently.

**Lemma 2.1** A Cannon-Thurston map from \(\tilde{Y}\) to \(\tilde{X}\) exists if the following condition is satisfied:

Given \(y_0 \in Y\), there exists a non-negative function \(M(N)\), such that \(M(N) \to \infty\) as \(N \to \infty\) and for all geodesic segments \(\lambda\) lying outside an \(N\)-ball around \(y_0 \in Y\) any geodesic segment in \(\Gamma_G\) joining the end-points of \(i(\lambda)\) lies outside the \(M(N)\)-ball around \(i(y_0) \in X\).

The above result can be interpreted as saying that a Cannon-Thurston map exists if the space of geodesic segments in \(Y\) embeds properly in the space of geodesic segments in \(X\).

### 2.2 \(i\)-bounded Geometry

We start with a hyperbolic surface \(S^h\) with or without punctures. The hyperbolic structure is arbitrary, but it is important that a choice be made. \(S\) will denote \(S^h\) minus a small enough neighborhood of the cusps.

Fix a finite collection \(\mathcal{C}\) of (geodesic representatives of) simple closed curves on \(S\). \(N_\epsilon(\sigma)\) will denote the \(\epsilon\)-neighborhood of a geodesic \(\sigma \in \mathcal{C}\).

\(N_\epsilon(\sigma)\) will denote an \(\epsilon\) neighborhood of \(\sigma_i \subset S^h\) for some \(\sigma_i \in \mathcal{C}\). \(\epsilon\) and the neighborhood of the cusps in \(S^h\) are chosen small enough so that

- 1. \(N_\epsilon(\sigma_i)\) is at least a distance of \(\epsilon\) from the cusps.
- 2. No two lifts of \(N_\epsilon(\sigma_i)\) to the universal cover \(S^h\) intersect.
Note that $S = S^h$ if $S$ has no cusps. Restrict the metric on $S^h$ to $S$ and equip $S$ with the resultant path-metric.

The Thin Building Block
For the construction of a thin block, $I$ will denote the closed interval $[0, 3]$. Now put a product metric structure on $S \times I$, which restricts to the path-metric on $S$ for each slice $S \times a, a \in I$ and the Euclidean metric on the $I$-factor. Let $B_i^c$ denote $(S \times I - N_{\epsilon}(\sigma_i) \times [1, 2])$. Equip $B_i^c$ with the path-metric.

For each resultant torus component of the boundary of $B_i^c$, perform Dehn filling on some $(1, n_i)$ curve, which goes $n_i$ times around the meridian and once round the longitude. $n_i$ will be called the twist coefficient. The metric on the solid torus $\Theta_i$ glued in is arranged in such a way that it is isometric to the quotient of a neighborhood of a bi-infinite hyperbolic geodesic by a hyperbolic isometry. Further, the $(1, n_i)$-curve is required to bound a totally geodesic hyperbolic disk. In fact, we might as well foliate the boundary of $\Theta_i$ by translates (under hyperbolic isometries) of the meridian, and demand that each bounds a totally geodesic disk. Since there is no canonical way to smooth out the resulting metric, we leave it as such. $\Theta_i$ equipped with this metric will be called a Margulis tube in keeping with the analogy from hyperbolic space.

The resulting copy of $S \times I$ obtained, equipped with the metric just described, is called a thin building block and is denoted by $B_i$.

Thick Block
Fix constants $D, \epsilon$ and let $\mu = [p, q]$ be an $\epsilon$-thick Teichmuller geodesic of length less than $D$. $\mu$ is $\epsilon$-thick means that for any $x \in \mu$ and any closed geodesic $\eta$ in the hyperbolic surface $S^h_x$ over $x$, the length of $\eta$ is greater than $\epsilon$. Now let $B^h$ denote the universal curve over $\mu$ reparametrized such that the length of $\mu$ is covered in unit time. Let $B$ denote $B^h$ minus a neighborhood of the cusps. Thus $B = S \times [0, 1]$ topologically.

A small enough neighborhood of the cusps of $S^h$ is fixed. $S^h \times \{x\}, x \in [0, 1]$ is given the hyperbolic structure $S^h_0$ corresponding to the point at distance $d_{Teich}(p, q)$ from $p$ along $\mu$ ($d_{Teich}$ denotes Teichmuller metric). A neighborhood of the cusps of $S^h$ having been fixed, we remove the images under the Teichmuller map (from $S^h_0$ to $S^h_x$) of this neighborhood (having first fixed a neighborhood of the cusps of $S^h_0$ as the image under the Teichmuller map from $S^h$).

The resultant manifold $B$ (possibly with boundary) is given the path metric and is called a thick building block.
Note that after acting by an element of the mapping class group, we might as well assume that \( \mu \) lies in some given compact region of Teichmuller space. This is because the marking on \( S \times \{0\} \) is not important, but rather its position relative to \( S \times \{1\} \). Further, since we shall be constructing models only up to quasi-isometry, we might as well assume that \( S^h \times \{0\} \) and \( S^h \times \{1\} \) lie in the orbit under the mapping class group of some fixed base surface. Hence \( \mu \) can be further simplified to be a Teichmuller geodesic joining a pair \((p,q)\) amongst a finite set of points in the orbit of a fixed hyperbolic surface \( S^h \).

**The Model Manifold**

Note that the boundary of a thin block \( B_i \) consists of \( S \times \{0,3\} \) and the intrinsic path metric on each such \( S \times \{0\} \) or \( S \times \{3\} \) is equivalent to the path metric on \( S \). Also, the boundary of a thick block \( B \) consists of \( S \times \{0,1\} \), where \( S^h_0, S^h_1 \) lie in some given bounded region of Teichmuller space. The intrinsic path metrics on each such \( S \times \{0\} \) or \( S \times \{1\} \) is the path metric on \( S \).

The model manifold of i-bounded geometry is obtained from \( S \times J \) (where \( J \) is a sub-interval of \( \mathbb{R} \), which may be semi-infinite or bi-infinite. In the former case, we choose the usual normalisation \( J = [0,\infty) \) ) by first choosing a sequence of blocks \( B_i \) (thick or thin) and corresponding intervals \( I_i = [0,3] \) or \( [0,1] \) according as \( B_i \) is thick or thin. The metric on \( S \times I_i \) is then declared to be that on the building block \( B_i \). Thus we have,

**Definition:** A manifold \( M \) homeomorphic to \( \tilde{S} \times J \), where \( J = [0,\infty) \) or \( J = (-\infty,\infty) \), is said to be a model of i-bounded geometry if

1. there is a fiber preserving homeomorphism from \( M \) to \( \tilde{S} \times J \) that lifts to a quasi-isometry of universal covers

2. there exists a sequence \( I_i \) of intervals (with disjoint interiors) and blocks \( B_i \) where the metric on \( S \times I_i \) is the same as that on some building block \( B_i \)

3. \( \bigcup_i I_i = J \)

The figure below illustrates schematically what the model looks like. Filled squares correspond to torii along which hyperbolic Dehn surgery is
performed. The blocks which have no filled squares are the thick blocks and those with filled squares are the thin blocks.

![Diagram of blocks]

**Figure 1: Model of i-bounded geometry (schematic)**

**Definition:** A manifold $M$ homeomorphic to $S \times J$, where $J = [0, \infty)$ or $J = (-\infty, \infty)$, is said to have **i-bounded geometry** if there exists $K$, $\epsilon > 0$ such that the universal cover $\tilde{M}$ is $K$, $\epsilon$ quasi-isometric to a model manifold of i-bounded geometry.

Further, a geometrically tame hyperbolic 3-manifold is said to have **i-bounded geometry** if each end has i-bounded geometry.

**Note:** We shall later have occasion to introduce a different model, called the **graph model**

**The Punctured Torus**

In [18], Minsky constructs a model manifold for arbitrary punctured torus groups that motivates the above definitions. For him, $S^h$ is the square punctured torus. $C$ consists of precisely two shortest curves $a, b$ of equal length on $S^h$. $C_i$ is the singleton set \{a\} for $i$ even and the set \{b\} for $i$ odd. The numbers $n$ corresponding to the surgery coefficients correspond to the number of Dehn twists performed about the $i$th curve. Thus, we see from Minsky’s construction of the model manifold for punctured torus groups that all punctured torus groups give rise to manifolds of **i-bounded geometry**

**Alternate Description of i-bounded geometry**

We could weaken the definition of thin blocks in models of i-bounded geometry by requiring that a family $C$ of disjoint simple closed curves (rather than a single simple closed curve) are modified by hyperbolic Dehn surgery. This gives rise to an equivalent definition.

To see this, add on as many blocks (indexed by $j$) of $S \times I$ as there are curves in $C$ (this number is bounded in terms of the genus of $S$). Then
isotope Margulis tubes to different levels by a bi-Lipschitz map away from the tubes. The universal covers of the original $S \times I$ and the new $S \times \bigcup_j I_j$ are quasi-isometric.

Hence, it does not multiply examples to allow a family $\mathcal{C}$ rather than a single curve.

3 Relative Hyperbolicity

In this section, we shall recall first certain notions of relative hyperbolicity due to Farb [8]. Using these, we shall derive certain Lemmas that will be useful in studying the geometry of the universal covers of building blocks.

3.1 Electric Geometry

Given some $\sigma$, we construct a pseudometric, on $S$ by defining

- the length of any path that lies along $\sigma$ to be zero,
- the length of any path $[a, b]$ that misses all such geodesics in its interior $(a, b)$ to be the hyperbolic length, and
- the length of any other path to be the sum of lengths of pieces of the above two kinds.

This allows us to define distances by taking the infimum of lengths of paths joining pairs of points and gives us a path pseudometric, which we call the electric metric. The electric metric also allows us to define geodesics. Let us call $S$ equipped with the above pseudometric $S_{el}$.

We shall be interested in the universal cover $\tilde{S}_{el}$ of $S_{el}$. Paths in $S_{el}$ and $\tilde{S}_{el}$ will be called electric paths (following Farb [8]). Geodesics and quasigeodesics in the electric metric will be called electric geodesics and electric quasigeodesics respectively.

**Definitions:**

- A path $\gamma : I \to Y$ in a path metric space $Y$ is an ambient $K$-quasigeodesic if we have

  $$L(\beta) \leq KL(A) + K$$

  for any subsegment $\beta = \gamma|_{[a, b]}$ and any rectifiable path $A : [a, b] \to Y$ with the same endpoints.

- $\gamma$ is said to be an electric $K, \epsilon$-quasigeodesic in $\tilde{S}_{el}$ without backtracking if $\gamma$ is an electric $K$-quasigeodesic in $\tilde{S}_{el}$ and $\gamma$ does not return to any any lift $N_\epsilon(\sigma) \subset \tilde{S}_{el}$ of $N_\epsilon(\sigma)$ after leaving it.
A hyperbolic geodesic \( \lambda \) may follow a lift \( \tilde{\sigma} \) for a long time \textit{without/ after/ before/ before and after} intersecting it. This is why in the definition of quasigeodesics without backtracking, we take \( N_{e}(\tilde{\sigma}) \) rather than \( \tilde{\sigma} \) itself.

A similar definition can be given in the case of manifolds with cusps. Here electrocuted sets correspond to horodisks (lifts of cusps). More generally, we can consider \( X \) to be a convex subset of \( \mathbb{H}^{n} \) and \( H \) to be a collection of uniformly separated horoballs in \( X \) based on points of \( \partial X \) (i.e. they are the intersection with \( X \) of certain horoballs in \( \mathbb{H}^{n} \) whose boundary point lies in \( \partial X \)).

**Definition:** Let \( X \) be a convex subset of \( \mathbb{H}^{n} \) and \( H \) a collection of uniformly separated horoballs \( H \). Let \( Y \) be the complement \( X - \{ H : H \in H \} \). \( \gamma \) is said to be an ambient \( K \)-quasigeodesic (resp. a \( K \)-quasigeodesic in \( X \)) \textit{without backtracking} if

\( \cdot \) \( \gamma \) is an ambient \( K \)-quasigeodesic in \( Y \) (resp. a \( K \)-quasigeodesic in \( X \))

\( \cdot \) \( \gamma \) is obtained from a \( K \)-quasigeodesic in \( X \) by replacing each maximal subsegment with end-points on a horosphere by a quasigeodesic lying on the surface of the horosphere (resp. \( \gamma \) does not return to any horoball \( H \) after leaving it.)

We collect together certain facts about the electric metric that Farb proves in [8]. \( N_{R}(Z) \) will denote the \( R \)-neighborhood about the subset \( Z \) in the hyperbolic metric. \( N_{R}^{e}(Z) \) will denote the \( R \)-neighborhood about the subset \( Z \) in the electric metric.

**Lemma 3.1** (Lemma 4.5 and Proposition 4.6 of [8])

1. **Electric quasi-geodesics electrically track hyperbolic geodesics:** Given \( P > 0 \), there exists \( K > 0 \) with the following property: For some \( \bar{S}_{i} \), let \( \beta \) be any electric \( P \)-quasigeodesic without backtracking from \( x \) to \( y \), and let \( \gamma \) be the hyperbolic geodesic from \( x \) to \( y \). Then \( \beta \subset N^{e}_{R}(\gamma) \).

2. **Hyperbolicity:** There exists \( \delta \) such that each \( \bar{S}_{el} \) is \( \delta \)-hyperbolic, independent of the curve \( \sigma \in \mathcal{C} \) whose lifts are electrocuted.

**Note:** In [8], Farb proves the above Lemma for horospheres rather than geodesics. There is however, an easy trick to convert geodesics to horocycles as follows:
For each geodesic $\sigma_i$, construct a geometrically finite hyperbolic 3-manifold $M_i$, in which the curve $\sigma_i$ is an (accidental) parabolic, i.e. one boundary component of $M_i$ corresponds to the surface $S^h$ and on the other component the curve become parabolic. Removing horoball neighborhoods of cusps, we get a manifold quasi-isometric to $S$ (the quasi-isometry is uniform, i.e. independent of $i$, since only finitely many choices are possible for $C_i$). The electric pseudo-metric obtained by putting the zero metric on horospheres is easily seen to be quasi-isometric to the metric on $S_i$. As a consequence, all of Farb’s results go through with very minor modifications.

An alternate approach is to follow Lemmas 4.4 through 4.10 of [8] with geodesics replacing horospheres, and exactly the same arguments apply. However, we have to state the results a little carefully, to avoid some obvious errors. This is particularly necessary for the Lemmas 4.8 through 4.10 of [8], where the corresponding notion of ‘bounded penetration’ for geodesics is a little different.

Farb gives more precise information regarding the tracking properties mentioned in Lemma 3.1 above. But before we go into this, we want to make the notion of penetration more precise. Hyperbolic geodesics may come arbitrarily close to an electrocuted geodesic without meeting it. However, from the first part of Lemma 3.1, electric geodesics lie electrically close to the hyperbolic geodesic. This is where we need a neighborhood of the electrocuted geodesic rather than the geodesic itself. Recall that we chose an $\epsilon$ such that the $\epsilon$-neighborhoods of the electrocuted geodesics are $\epsilon$-separated. This allows us to give the following modified versions of Lemmas 4.8 - 4.10 of [8].

**Lemma 3.2** Let $\beta$ be an electric $P$-quasigeodesic without backtracking and $\gamma$ a hyperbolic geodesic, both joining $x, y$ in some $S_{el}$. Then, given $\epsilon$ there exists $D = D(P, \epsilon)$ such that

1. Similar Intersection Patterns 1: if precisely one of $\{\beta, \gamma\}$ meets an $\epsilon$-neighborhood $N_{\epsilon}(\tilde{\sigma})$ of an electrocuted geodesic $\tilde{\sigma}$, then the length (measured in the intrinsic path-metric on $N_{\epsilon}(\tilde{\sigma})$) from the first (entry) point to the last (exit) point is at most $D$.

2. Similar Intersection Patterns 2: if both $\{\beta, \gamma\}$ meet some $N_{\epsilon}(\tilde{\sigma})$ then the length (measured in the intrinsic path-metric on $N_{\epsilon}(\tilde{\sigma})$) from the
entry point of $\beta$ to that of $\gamma$ is at most $D$; similarly for exit points.

In fact, much of what Farb proved in [8] goes through under considerably weaker assumptions. In [8] the theorems were proven in the particular context of a pair $(X, \mathcal{H})$, where $X$ is a Hadamard space of pinched negative curvature with the interiors of a family of horoballs $\mathcal{H}$ removed. Then $\mathcal{H}$ can be regarded as a collection of horospheres in $X$ separated by a minimum distance from each other. In this situation, $X$ is not a hyperbolic metric space itself, but is hyperbolic relative to a collection of separated horospheres. Alternately, $X$ may be regarded as hyperbolic space itself, and $\mathcal{H}$ as a separated collection of horoballs. Note that this gives an equivalent description, and moreover, one that is easier to formulate abstractly.

We consider therefore a hyperbolic metric space $X$ and a collection $\mathcal{H}$ of (uniformly) $C$-quasiconvex uniformly separated subsets, i.e. there exists $D > 0$ such that for $H_1, H_2 \in \mathcal{H}$, $d_X(H_1, H_2) \geq D$. In this situation $X$ is hyperbolic relative to the collection $\mathcal{H}$. The result in this form is due to Klarreich [13]. However, the property of Bounded Horosphere Penetration (BHP) or Bounded Coset Penetration (BCP) was not abstracted out in Klarreich’s proof as it was not necessary. What is essential for BCP (or BHP) to go through has been abstracted out by Bowditch [3] [2] in the case that the collection $\mathcal{H}$ is a collection of geodesics or horocycles in a Farey graph. But though these things are available at the level of folklore, an explicit statement seems to be lacking. The crucial condition can be isolated as per the following definition:

Definition: A collection $\mathcal{H}$ of uniformly $C$-quasiconvex sets in a $\delta$-hyperbolic metric space $X$ is said to be mutually D-cobounded if for all $H_i, H_j \in \mathcal{H}$, $\pi_i(H_j)$ has diameter less than $D$, where $\pi_i$ denotes a nearest point projection of $X$ onto $H_i$. A collection is mutually cobounded if it is mutually D-cobounded for some $D$.

Mutual coboundedness was proven for horoballs by Farb in Lemma 4.7 of [8] and by Bowditch in stating that the projection of the link of a vertex onto another [2] has bounded diameter in the link. However, the comparability of intersection patterns in this context needs to be stated a bit more carefully. We give the general version of Farb’s theorem below and refer to [8] and Klarreich [13] for proofs.

Lemma 3.3 (See Lemma 4.5 and Proposition 4.6 of [8]) Given $\delta, C, D$ there
exists $\Delta$ such that if $X$ is a $\delta$-hyperbolic metric space with a collection $\mathcal{H}$ of $C$-quasiconvex $D$-separated sets, then,

1. Electric quasi-geodesics electrically track hyperbolic geodesics: Given $P > 0$, there exists $K > 0$ with the following property: Let $\beta$ be any electric $P$-quasigeodesic from $x$ to $y$, and let $\gamma$ be the hyperbolic geodesic from $x$ to $y$. Then $\beta \subset N_K(\gamma)$.

2. $\gamma$ lies in a hyperbolic $K$-neighborhood of $N_0(\beta)$, where $N_0(\beta)$ denotes the zero neighborhood of $\beta$ in the electric metric.

3. Hyperbolicity: $X$ is $\Delta$-hyperbolic.

We shall need to give a general definition of geodesics and quasigeodesics without backtracking.

**Definitions:** Given a collection $\mathcal{H}$ of $C$-quasiconvex, $D$-separated sets and a number $\epsilon$ we shall say that a geodesic (resp. quasigeodesic) $\gamma$ is a geodesic (resp. quasigeodesic) **without backtracking** with respect to $\epsilon$ neighborhoods if $\gamma$ does not return to $N_\epsilon(H)$ after leaving it, for any $H \in \mathcal{H}$. A geodesic (resp. quasigeodesic) $\gamma$ is a geodesic (resp. quasigeodesic) **without backtracking** if it is a geodesic (resp. quasigeodesic) without backtracking with respect to $\epsilon$ neighborhoods for some $\epsilon \geq 0$.

**Note:** For strictly convex sets, $\epsilon = 0$ suffices, whereas for convex sets any $\epsilon > 0$ is enough.

Item (2) in the above Lemma is due to Klarreich [13], where the proof is given for $\beta$ an electric geodesic, but the same proof goes through for electric quasigeodesics.

**Note:** For the above lemma, the hypothesis is that $\mathcal{H}$ consists of uniformly quasiconvex, mutually separated sets. Mutual coboundedness has not yet been used. We introduce **co-boundedness** in the next lemma.

**Lemma 3.4** Suppose $X$ is a $\delta$-hyperbolic metric space with a collection $\mathcal{H}$ of $C$-quasiconvex $K$-separated $D$-mutually cobounded subsets. There exists $\epsilon_0 = \epsilon_0(C, K, D, \delta)$ such that the following holds:

17
Let \( \beta \) be an electric \( P \)-quasigeodesic without backtracking and \( \gamma \) a hyperbolic geodesic, both joining \( x, y \). Then, given \( \epsilon \geq \epsilon_0 \) there exists \( D = D(P, \epsilon) \) such that

1. Similar Intersection Patterns 1: if precisely one of \( \{\beta, \gamma\} \) meets an \( \epsilon \)-neighborhood \( N_\epsilon(H_1) \) of an electrocuted quasiconvex set \( H_1 \in \mathcal{H} \), then the length (measured in the intrinsic path-metric on \( N_\epsilon(H_1) \) ) from the entry point to the exit point is at most \( D \).

2. Similar Intersection Patterns 2: if both \( \{\beta, \gamma\} \) meet some \( N_\epsilon(H_1) \) then the length (measured in the intrinsic path-metric on \( N_\epsilon(H_1) \) ) from the entry point of \( \beta \) to that of \( \gamma \) is at most \( D \); similarly for exit points.

We summarise the two Lemmas 3.3 and 3.4 in forms that we shall use:

- If \( X \) is a hyperbolic metric space and \( \mathcal{H} \) a collection of uniformly quasiconvex separated subsets, then \( X \) is hyperbolic relative to the collection \( \mathcal{H} \).

- If \( X \) is a hyperbolic metric space and \( \mathcal{H} \) a collection of uniformly quasiconvex mutually cobounded separated subsets, then \( X \) is hyperbolic relative to the collection \( \mathcal{H} \) and satisfies Bounded Penetration, i.e. hyperbolic geodesics and electric quasigeodesics have similar intersection patterns in the sense of Lemma 3.4.

The relevance of co-boundedness comes from the following Lemma which is essentially due to Farb [8].

**Lemma 3.5** Let \( M^h \) be a hyperbolic manifold of i-bounded geometry, with Margulis tubes \( T_i \in \mathcal{T} \) and horoballs \( H_j \in \mathcal{H} \). Then the lifts \( T_i \) and \( H_j \) are mutually co-bounded.

The proof given in [8] is for a collection of separated horospheres, but the same proof works for neighborhoods of geodesics and horospheres as well.

A closely related theorem was proved by McMullen (Theorem 8.1 of [16]).

As usual, \( N_R(Z) \) will denote the \( R \)-neighborhood of the set \( Z \).

Let \( \mathcal{H} \) be a locally finite collection of horoballs in a convex subset \( X \) of \( \mathbb{H}^n \) (where the intersection of a horoball, which meets \( \partial X \) in a point, with \( X \) is called a horoball in \( X \)).

18
Definition: The $\epsilon$-neighborhood of a bi-infinite geodesic in $\mathbb{H}^n$ will be called a thickened geodesic.

**Theorem 3.6** [16] Let $\gamma: I \to X \setminus H$ be an ambient $K$-quasigeodesic (for $X$ a convex subset of $\mathbb{H}^n$) and let $H$ denote a uniformly separated collection of horoballs and thickened geodesics. Let $\eta$ be the hyperbolic geodesic with the same endpoints as $\gamma$. Let $H(\eta)$ be the union of all the horoballs and thickened geodesics in $H$ meeting $\eta$. Then $\eta \cup H(\eta)$ is (uniformly) quasiconvex and $\gamma(I) \subset B_R(\eta \cup H(\eta))$, where $R$ depends only on $K$.

As in Lemmas 3.3 and 3.4, this theorem goes through for mutually cobounded separated uniformly quasiconvex sets $H$.

A special kind of geodesic without backtracking will be necessary for universal covers of surfaces with some electric metric.

Let $\lambda_e$ be an electric geodesic in some $(\hat{S}, d_e)$ for $\hat{S}$ equipped with some electric metric obtained by electrocuting a collection of mutually cobounded separated geodesics. Then, each segment of $\lambda_e$ between electrocuted geodesics is perpendicular to the electrocuted geodesics that it starts and ends at. We shall refer to these segments of $\lambda_e$ as **complementary segments** because they lie in the complement of the electrocuted geodesics. Let $a_\eta, b_\eta$ be the points at which $\lambda_e$ enters and leaves the electrocuted (bi-infinite) geodesic $\eta$. Let $[a, b]_\eta$ denote the geodesic segment contained in $\eta$ joining $a, b$. Segments like $[a, b]_\eta$ shall be referred to as **interpolating segments**. The union of the **complementary segments** along with the **interpolating segments** gives rise to a preferred representative of geodesics joining the end-points of $\lambda_e$; in fact it is the unique quasigeodesic without backtracking whose underlying set represents an electric geodesic joining the end-points of $\lambda_e$. Such a representative of the class of $\lambda_e$ shall be called the **canonical representative** of $\lambda_e$. Further, the underlying set of the canonical representative in the hyperbolic metric shall be called the **electro-ambient representative** $\lambda_q$ of $\lambda_e$. Since $\lambda_q$ will turn out to be a hyperbolic quasigeodesic, we shall also call it an **electro-ambient quasigeodesic**. See Figure 2 below:
Now, let $\lambda_h$ denote the hyperbolic geodesic joining the end-points of $\lambda_e$. By Lemma 3.2, $\lambda_h$ and $\lambda_e$, and hence $\lambda_h$ and $\lambda_q$ have similar intersection patterns with $N_c(\eta)$ for electrocuted geodesics $\eta$. Also, $\lambda_h$ and $\lambda_q$ track each other off $N_c(\eta)$. Further, each interpolating segment of $\lambda_q$ being a hyperbolic geodesic, it follows (from the ‘$K$-fellow-traveller’ property of hyperbolic geodesics starting and ending near each other) that each interpolating segment of $\lambda_q$ lies within a $(K + 2\varepsilon)$ neighborhood of $\lambda_h$. Again, since each segment of $\lambda_q$ that does not meet an electrocuted geodesic that $\lambda_h$ meets is of uniformly bounded (by $C$ say) length, we have finally that $\lambda_q$ lies within a $(K + C + 2\varepsilon)$ neighborhood of $\lambda_h$. Finally, since $\lambda_q$ is an electro-ambient representative, it does not backtrack. Hence we have the following:

**Lemma 3.7** There exists $(K, \varepsilon)$ such that each electro-ambient representative of an electric geodesic is a $(K, \varepsilon)$ hyperbolic quasigeodesic.

In the above form, electro-ambient quasigeodesics are considered only in the context of surfaces and closed geodesics on them. This can be generalised considerably. Let $X$ be a $\delta$-hyperbolic metric space, and $\mathcal{H}$ a family of $C$-quasiconvex, $D$-separated, $k$-cobounded collection of subsets. Then by Lemma 3.3, $X_{el}$ obtained by electrocuting the subsets in $\mathcal{H}$ is a $\Delta = \Delta(\delta, C, D)$-hyperbolic metric space. Now, let $\alpha = [a, b]$ be a hyperbolic geodesic in $X$ and $\beta$ be an electric $P$-quasigeodesic without backtracking joining $a, b$. Replace each maximal subsegment (with end-points $p, q$, say) of $\beta$ lying within some $H \in \mathcal{H}$ by a hyperbolic interpolating geodesic $[p, q]$. The resulting connected path $\beta_q$ is called an electro-ambient quasigeodesic in $X$. The following Lemmas justify the terminology:
Lemma 3.8  Given $\delta, D, C, k, P$ as above, there exists $C_3$ such that the following holds:
Let $\alpha, \beta$ be as above. Then $\alpha$ lies in a $C_3$ neighborhood of $\beta_q$

Proof: The proof idea is similar to that for surfaces and geodesics.
By Lemma 3.3, item (2), there exists $C_0$ such that $\alpha$ lies in a (hyperbolic) $C_0$-neighborhood of $N_0(\beta_q)$. Further, by bounded penetration following from co-boundedness, there exists $C_1$ such that if some interpolating geodesic $[p, q]$ in $H$ is of length greater than $C_1$, then there exist $p_1, q_1 \in H \cap \alpha$ such that
$d(p, p_1) \leq C_1$
$d(q, q_1) \leq C_1$
$d(p_1, q_1)$ is maximal over all pairs $u, v \in H \cap \alpha$

Hence, by the fellow traveller property, there exists $C_2$ such that the hyperbolic geodesic $[p_1, q_1] \subset \alpha$ lies in a $C_2$-neighborhood of $[p, q]$ and hence $\beta_q$.

Now, if $x \in \alpha$, $x$ lies in a $C_0$ neighborhood of $N_0(\beta_q)$. Let $y \in N_0(\beta_q)$ be the point nearest to $x$. If $y$ lies on $\beta - H$, then $d(x, \beta_q) \leq C_0$. Else, $y$ lies on some $H$. Two cases arise:
Case 1: $\beta$ and hence $\beta_q$ do not penetrate $H$ for more than $C_1$. In this case, there exists $y \in \beta - H$, such that $d(x, y) \leq C_0 + C_1$.
Case 2: $\beta$ and hence $\beta_q$ do penetrate $H$ for more than $C_1$ and therefore an interpolating geodesic $[p, q]$ of length greater than $C_1$ exists. Hence there exists a maximal subsegment of $\alpha$ within a $C_2$ neighborhood of $[p, q]$. From this it follows easily that $x$ lies in a $C_2$ neighborhood of $\beta_q$.
Thus $\alpha$ lies in a (uniformly) bounded $C_3$-neighborhood of $\beta_q$. (Here, $C_3 = C_0 + C_1 + C_2$ suffices.) $\square$

In fact, more is true. $\beta_q$ is a hyperbolic quasigeodesic. But to see this needs a bit more work. For the sake of concreteness, and to simplify the exposition, we assume that $X$ is a complete simply connected manifold of pinched negative curvature. Let $\pi_\alpha$ denote the nearest point retraction onto $\alpha$. Since $\beta_q$ is connected, joins the end-points of $\alpha$ and $\pi_\alpha$ is continuous, $\pi_\alpha(\beta_q) = \alpha$.

Claim: There exists $D > 0$ such that any two points $u, v$ with $\pi_\alpha(u) = \pi_\alpha(v) = w$ satisfy $d(u, v) \leq D$.

Proof of Claim: The loop that goes from $w$ to $u$ by a hyperbolic path of length less than $C_3$ (from Lemma 3.8), then from $u$ to $v$ along $\beta_q$ and then back to $w$ by a hyperbolic path of less than $C_3$ is a $C_4$-quasigeodesic (for
some uniform $C_4$). It can also be converted into a path without backtracking. Clearly, the geodesic joining the end-points of the path (a loop) has length zero. By Lemma 3.4 the path penetrates each $H \in \mathcal{H}$ by a uniformly bounded amount $C_5$. Hence, there exists a uniform constant $C_6$ depending on $C_5$ and $D$, such that the loop has (hyperbolic) length less than $C_6$. The Claim follows. □

In the same way, it follows that given $D_0$ there exists $D_1$, such that if $d(\pi_\alpha(u), \pi_\alpha(v)) \leq D_0$ then $d(u, v) \leq D_1$.

From the Claim above, it follows that $\beta_q$ also must lie in a bounded neighborhood of $\alpha$ (else there will have to be long detours along $\beta_q$ starting and ending at a distance less than $2C_3$ from each other). Further, $\beta_q$ cannot have long pieces starting and ending close to each other for the same reason. Thus $\beta_q$ lying in a bounded neighborhood of $\alpha$ must ‘progress’. In other words $\beta_q$ must be a hyperbolic quasigeodesic. We state this formally below:

**Lemma 3.9** There exist $K, \epsilon$ depending on $\delta, D, C, k, P$, such that $\beta_q$ is a $(K, \epsilon)$-quasigeodesic.

In our proof of Lemma 3.8, we have used the hypothesis that the collection $\mathcal{H}$ of qc sets is a mutually cobounded collection. However, this hypothesis can be relaxed. The proof is exactly the same as Klarreich’s proof of Proposition 4.3 of [13], which has been stated here as Item (2) in Lemma 3.3 above. We state this below and refer to Proposition 4.3 of [13] for the relevant details:

**Lemma 3.10** Given $\delta, C, D, P$ there exists $C_3$ such that the following holds: Let $(X, d)$ be a $\delta$-hyperbolic metric space and $\mathcal{H}$ a family of $C$-quasiconvex, $D$-separated collection of quasiconvex subsets. Let $(X, d_e)$ denote the electric space obtained by electrocuting elements of $\mathcal{H}$. Then, if $\alpha, \beta_q$ denote respectively a hyperbolic geodesic and an electro-ambient $P$-quasigeodesic with the same end-points, then $\alpha$ lies in a (hyperbolic) $C_3$ neighborhood of $\beta_q$.

**Note:** The above Lemma generalises Klarreich’s Property (2) in Lemma 3.3) by replacing $N_0(\beta)$ with $\beta_q$. The former set can be quite large, but $\beta_q$ is much smaller, containing only one geodesic segment in $H$ rather than all of $H$. It is the introduction of the notion of electro-ambient quasigeodesic that makes for this generalisation. However, Lemma 3.9 is false in this generality. The idea is that two elements of $\mathcal{H}$ might have geodesics that are parallel (i.e. close to each other) for their entire length. Then an electro-ambient
quasigeodesic might look like two adjacent edges of a thin triangle. This is precluded in Lemma 3.9 by the hypothesis of coboundedness. We shall not be needing this stronger Lemma 3.10 in this paper and it is included here for completeness.

Another Lemma which we shall be using follows from the proof of the Claim in the proof of Lemma 3.9 above.

**Lemma 3.11** Given $D_0$ there exists $D_1$ such that if $\alpha$ be a loop without backtracking in $X_{el}$ with electric length less than $D_0$ and further, if $\alpha \cap H$ is a geodesic for each $H \in \mathcal{H}$, then the hyperbolic length of $\alpha$ is less than $D_1$.

### 3.2 Dehn twists are electric isometries

Let $S_i$ be a surface whose path-pseudometric is obtained from a (fixed) hyperbolic metric by electrocuting the geodesic $\sigma_i$ in $\mathcal{C}$. We can think of the Dehn twists as supported in the $\epsilon$-neighborhood $N_{\epsilon}(\sigma_i)$ and that these neighborhoods have been given the zero-metric. Denote the resultant electric metric on $S_i$ by $\rho_i$.

We want to show that any power of a Dehn twist about $\sigma_i$ induces an isometry of the surface $S_i$ equipped with $\rho_i$. Consider any two points $x, y \in S_i$. Let $\alpha$ be any path in general position with respect to $\sigma$ joining $x, y$. Look at the action of Dehn twist $tw$ about some curve $\sigma_i \in \mathcal{C}$ on $\alpha$. Let $\alpha$ meet $\sigma$ in $p_1, \ldots, p_k$. Let $tw(\alpha)$ be the path obtained from $\alpha$ by keeping it unchanged off $\sigma$ and for each intersection point $p_i$, we compose $\alpha$ with a path lying on $\sigma$ starting and ending at $p_i$ and traversing $\sigma$ once in the direction of the Dehn twist. Since the restriction $\rho_i|_{\sigma} = 0$, $\alpha$ and $tw(\alpha)$ have the same length. Hence, the length of the shortest path (geodesic) in the homotopy class (rel. end-points) of $tw(\alpha)$ is less than or equal to the length of the geodesic representative of the class of $\alpha$.

Again, let $\beta$ be any path in the homotopy class of $tw(\alpha)$. Then by acting by the reverse Dehn twist $tw^{-1}$ about $\sigma$, we find by an identical argument that the geodesic representative of the homotopy class of $\alpha$, which is the same as that of $tw^{-1}(\beta)$ has length less than or equal to the length of the geodesic representative of $\beta$.

Since $\beta$ and $tw(\alpha)$ are homotopic rel. endpoints, we conclude that $\alpha$ and $tw(\alpha)$ have geodesic representatives of the same length.

This proves
**Lemma 3.12** Let $t\omega^n$ denote a power of a Dehn twist about the curve $\sigma_i \in C$ and $\rho_i$ denote the electric metric on $S_i$. Then $t\omega^n$ induces an isometry of $(S_i, \rho_i)$. In particular, we may arrange $t\omega^n$ to take geodesics to geodesics.

The last statement in Lemma 3.12 has been put because geodesics are not uniquely defined in the usual sense in the electric metric. But a preferred path does exist, viz. the path which does not backtrack (or double back) on any $\sigma \in C_i$, i.e. restricted to $\sigma$ the path is a geodesic in the ordinary sense.

Everything in the above can be lifted to the universal cover $\tilde{S}_i$. We let $\tilde{t}w$ denote the lift of $tw$ to $\tilde{S}_i$. This gives

**Lemma 3.13** Let $\tilde{t}w^n$ denote a lift of $t\omega^n$ to $\tilde{S}_i$. Let $\tilde{\rho}_i$ denote the lifted electric metric on $\tilde{S}_i$. Then $\tilde{t}w^n$ induces an isometry of $(\tilde{S}_i, \tilde{\rho}_i)$. In particular, we may arrange $\tilde{t}w^n$ to take geodesics to geodesics.

### 3.3 Nearest-point Projections

We need the following basic lemmas from [23]. The following Lemma says nearest point projections in a $\delta$-hyperbolic metric space do not increase distances much.

**Lemma 3.14** (Lemma 3.1 of [23]) Let $(Y, d)$ be a $\delta$-hyperbolic metric space and let $\mu \subset Y$ be a $C$-quasiconvex subset, e.g. a geodesic segment. Let $\pi : Y \to \mu$ map $y \in Y$ to a point on $\mu$ nearest to $y$. Then $d(\pi(x), \pi(y)) \leq C_3 d(x, y)$ for all $x, y \in Y$ where $C_3$ depends only on $\delta, C$.

The next lemma says that quasi-isometries and nearest-point projections on hyperbolic metric spaces ‘almost commute’.

**Lemma 3.15** (Lemma 3.5 of [23]) Suppose $(Y_1, d_1)$ and $(Y_2, d_2)$ are $\delta$-hyperbolic. Let $\mu_1$ be some geodesic segment in $Y_1$ joining $a, b$ and let $p$ be any vertex of $Y_1$. Also let $q$ be a vertex on $\mu_1$ such that $d_1(p, q) \leq d_2(p, x)$ for $x \in \mu_1$. Let $\phi$ be a $(K, \epsilon)$ - quasimetric embedding from $Y_1$ to $Y_2$. Let $\mu_2$ be a geodesic segment in $Y_2$ joining $\phi(a)$ to $\phi(b)$. Let $\tau$ be a point on $\mu_2$ such that $d_2(\phi(p), \tau) \leq d_2(\phi(p), x)$ for $x \in \mu_2$. Then $d_2(r, \phi(q)) \leq C_4$ for some constant $C_4$ depending only on $K, \epsilon$ and $\delta$.

**Sketch of Proof:** (See [23] for details.) $[p, q] \cup \mu_1$ is called a **tripod**. Then $[p, q] \cup [q, b], [p, q] \cup [q, a]$ and $[a, b]$ are all quasi-geodesics. Hence after
acting by \( \phi \) they map to quasigeodesics. In particular, \( \phi(q) \) must lie close to the image under \( \phi \) of each of \( [p, q] \cup [q, b], [p, q] \cup [q, a] \) and \( [a, b] \). Hence it must lie close to each of \( [\phi(a), \phi(b)], [\phi(a), \phi(p)] \) and \( [\phi(b), \phi(p)] \). Again, if \( \phi(a), \phi(b), \phi(p) \), \( z \) form the four points of a tripod (where \( z \) is a nearest point projection of \( \phi(p) \) onto the geodesic joining \( \phi(a), \phi(b) \)), then \( z \) too must lie close to each of \( [\phi(a), \phi(b)], [\phi(a), \phi(p)] \) and \( [\phi(b), \phi(p)] \).

The result follows by thinness of hyperbolic triangles. \( \Box \)

For our purposes we shall need the above Lemma for quasi-isometries from \( \tilde{S}_a \) to \( \tilde{S}_b \) for two different hyperbolic structures on the same surface. We shall also need it for the electrocutered surfaces obtained in Lemma 3.1.

Yet another property that we shall require for nearest point projections is that nearest point projections in the electric metric and in the hyperbolic metric almost agree. Let \( \tilde{S} = Y \) be the universal cover of a surface with the hyperbolic metric minus a neighborhood of cusps. Equip \( Y \) with the path metric \( d \) as usual. Then \( Y \) is either the hyperbolic plane (if \( \tilde{S} \) has no cusps) or else is quasi-isometric to a tree (the Cayley graph of a free group). Let \( \sigma \) be a closed geodesic on \( S \). Let \( d_e \) denote the electric metric on \( Y \) obtained by electrocuting the lifts of \( \sigma \). Now, let \( \mu = [a, b] \) be a hyperbolic geodesic on \( (Y, d) \) and let \( \mu_q \) denote the electro-ambient quasigeodesic joining \( a, b \). Let \( \pi \) denote the nearest point projection in \( (Y, d) \). Tentatively, let \( \pi_e \) denote the nearest point projection in \( (Y, d_e) \). Note that \( \pi_e \) is not well-defined. It is defined up to a bounded amount of discrepancy in the electric metric \( d_e \). But we would like to make \( \pi_e \) well-defined up to a bounded amount of discrepancy in the hyperbolic metric \( d \).

**Definition:** Let \( y \in Y \) and \( \mu_q \) be an electro-ambient representative of an electric geodesic \( \mu_e \) in \( (Y, d_e) \). Then \( \pi_e(y) = z \in \mu_q \) if the ordered pair \( \{d_e(y, \pi_e(y)), d(y, \pi_e(y))\} \) is minimised at \( z \).

Note that this gives us a definition of \( \pi_e \) which is ambiguous by a finite amount of discrepancy not only in the electric metric but also in the hyperbolic metric.

**Lemma 3.16** There exists \( C > 0 \) such that the following holds. Let \( \mu \) be a hyperbolic geodesic joining \( a, b \). Let \( \mu_e \) be the canonical representative of the electric geodesic joining \( a, b \). Also let \( \mu_q \) be the electro-ambient representative of \( \mu_e \). Let \( \pi_n \) denote the nearest point projection of \( \mathbb{H}^2 \) onto \( \mu \). \( d(\pi_n(y), \pi_e(y)) \) is uniformly bounded.

**Proof:** The proof is similar to that of Lemma 3.15, i.e. Lemma 3.5 of [23].
\[ [u, v]_h \text{ and } [u, v]_e \text{ will denote respectively the hyperbolic geodesic and the canonical representative of the electric geodesic joining } u, v \]

\[ [y, \pi_e(y)] \cup [\pi_e(y), a] \text{ is an electric quasigeodesic without backtracking. Hence as in the proof of Lemma 3.15, } [y, \pi_e(y)] \cup [\pi_e(y), a] \text{ lies in a bounded neighborhood of } [y, a]_h. \text{ In particular } \pi_e(y) \text{ lies in a bounded (hyperbolic) neighborhood of } [y, a]_h. \text{ By an identical argument } \pi_e(y) \text{ lies in a bounded neighborhood of } [y, b]_h. \text{ Again, since } \pi_e(y) \text{ lies on } \mu_e, \text{ therefore by Lemma 3.7, } \pi_e(y) \text{ lies in a bounded neighborhood of } \mu. \text{ Hence there exists } C > 0 \text{ such that } \pi_e(y) \in N_C([y, a]_h) \cap N_C([y, b]_h) \cap N_C(\mu).

Again, \([y, \pi_h(y)] \cup [\pi_h(y), a] \text{ is a hyperbolic quasigeodesic. Hence } [y, \pi_h(y)] \cup [\pi_h(y), a] \text{ lies in a bounded neighborhood of } [y, a]_h. \text{ In particular } \pi_h(y) \text{ lies in a bounded (hyperbolic) neighborhood of } [y, a]_h. \text{ By an identical argument } \pi_h(y) \text{ lies in a bounded neighborhood of } [y, b]_h. \text{ Again, since } \pi_h(y) \text{ lies on } \mu, \text{ therefore, trivially } \pi_h(y) \text{ lies in a bounded neighborhood of } \mu. \text{ Hence there exists } D > 0 \text{ such that } \pi_h(y) \in N_D([y, a]_h) \cap N_D([y, b]_h) \cap N_D(\mu).

Next, by hyperbolicity (thin-triangles) \( N_D([y, a]_h) \cap N_D([y, b]_h) \cap N_D(\mu) \text{ and } N_C([y, a]_h) \cap N_C([y, b]_h) \cap N_C(\mu) \) have diameter bounded by some \( D_1 \) depending on \( D, C \) and choosing \( D = C = \max(C, D) \), we get \( d(\pi_h(y), \pi_e(y)) \leq D_1 \).

\( \square \)

4 Universal Covers of Building Blocks and Electric Geometry

For most of this section (except the last subsection) we shall restrict our attention to closed surfaces and models corresponding to them. Let \( S = S^h \) be a closed surface with some hyperbolic structure. For surfaces with punctures \( S \) will denote \( S^h \) minus a neighborhood of cusps. This will call for some modifications of the exposition, but not the overall construction. Hence, for ease of exposition, we postpone dealing with cusps till the last subsection of this section.

4.1 Graph Model of Building Blocks

Thin Blocks

Given a geodesic segment \( \lambda \subset \bar{S} \) and a basic thin building block \( B \), let \( \lambda = [a, b] \subset \bar{S} \times \{0\} \) be a geodesic segment, where \( \bar{S} \times \{0\} B \), and \( B \) is obtained from \( S \times I \) by hyperbolic \((1, n)\) Dehn surgery on \( N_\xi(\sigma) \times [1, 2] \).
We shall now build a graph model for $B$ which will be quasi-isometric to an electriccuted version of the original model, where lifts of the curves $\sigma \in C$ which correspond to cores of Margulis tubes are electriccuted.

On $\bar{S} \times \{0\}$ and $\bar{S} \times \{3\}$ put the hyperbolic metric obtained from $S = S^h$. On $\bar{S} \times \{1\}$ and $\bar{S} \times \{2\}$ put the electric metric obtained by electriccuting the lifts of $\sigma$. This constructs 4 'sheets' of $\bar{S}$ comprising the 'horizontal skeleton' of the 'graph model' of $B$. Now for the vertical strands. On each vertical element of the form $x \times [0, 1]$ and $x \times [2, 3]$ put the Euclidean metric.

The resulting copy of $B$ will be called the graph model of a thin block.

Next, let $\phi$ denote the map induced on $\bar{S}$ by $tw_n^p$, the $n$-fold Dehn twist along $\sigma$. Join each $x \times \{1\}$ to $\phi(x) \times \{2\}$ by a Euclidean segment of length 1.

**Thick Block**

For a thick block $B = \bar{S} \times [0, 1]$, recall that $B$ is the universal curve over a 'thick' Teichmuller geodesic $\lambda_{Teich} = [a, b]$ of length less than some fixed $D > 0$. Each $\bar{S} \times \{x\}$ is identified with the hyperbolic surface over $(a + \frac{\pi}{b-a})$ (assuming that the Teichmuller geodesic is parametrized by arc-length).

Here $\bar{S} \times \{0\}$ is identified with the hyperbolic surface corresponding to $a$, $\bar{S} \times \{1\}$ is identified with the hyperbolic surface corresponding to $b$ and each $(x, a)$ is joined to $(x, b)$ by a segment of length 1.

The resulting model of $B$ is called a graph model of a thick block.

**Admissible Paths**

Admissible paths consist of the following:

1. Horizontal segments along some $\bar{S} \times \{i\}$ for $i = \{0, 1, 2, 3\}$ (thin blocks) or $i = \{0, 1\}$ (thick blocks).

2. Vertical segments $x \times [0, 1]$ or $x \times [2, 3]$ for thin blocks or $x \times [0, 1]$ for thick blocks.

3. Vertical segments of length 1 joining $x \times \{1\}$ to $\phi(x) \times \{2\}$ for thin blocks.

**4.2 Construction of Quasiconvex Sets for Building Blocks**

In the next section, we will construct a set $B_\lambda$ containing $\lambda$ and a retraction $\Pi_\lambda$ of $M$ onto it. $\Pi_\lambda$ will have the property that it does not stretch distances much. This will show that $B_\lambda$ is quasi-isometrically embedded in $M$.  

27
In this subsection, we describe the construction of $B_{\lambda}$ restricted to a building block $B$.

Construction of $B_{\lambda}(B)$ - Thick Block

Let the thick block be the universal curve over a Teichmuller geodesic $[\alpha, \beta]$. Let $S_{\alpha}$ denote the hyperbolic surface over $\alpha$ and $S_{\beta}$ denote the hyperbolic surface over $\beta$.

First, let $\lambda = [a, b]$ be a geodesic segment in $\tilde{S}$. Let $\lambda_{B0}$ denote $\lambda \times \{0\}$.

Next, let $\phi$ be the lift of the 'identity' map from $S_{\alpha}$ to $\tilde{S}$. Let $\Phi$ denote the induced map on geodesics and let $\Phi(\lambda)$ denote the hyperbolic geodesic joining $\phi(a), \phi(b)$. Let $\lambda_{B1}$ denote $\Phi(\lambda) \times \{1\}$.

For the universal cover $\tilde{B}$ of the thick block $B$, define:

$$B_{\lambda}(B) = \bigcup_{i=0,1} \lambda_{Bi}$$

**Definition:** Each $\tilde{S} \times i$ for $i = 0, 1$ will be called a horizontal sheet of $\tilde{B}$ when $B$ is a thick block.

Construction of $B_{\lambda}(B)$ - Thin Block

First, recall that $\lambda = [a, b]$ is a geodesic segment in $\tilde{S}$. Let $\lambda_{B0}$ denote $\lambda \times \{0\}$.

Next, let $\lambda_{el}$ denote the electric geodesic joining $a, b$ in the electric pseudo-metric on $\tilde{S}$ obtained by electrocuting lifts of $\sigma$. Let $\lambda_{B1}$ denote $\lambda_{el} \times \{1\}$.

Third, recall that $\phi$ is the lift of the Dehn twist $tw_{\mu}^n$ to $\tilde{S}$ equipped with the electric metric. Let $\Phi$ denote the induced map on geodesics, i.e. if $\mu = [x, y] \subset (\tilde{S}, d_{el})$, then $\Phi(\mu) = [\phi(x), \phi(y)]$ is the geodesic joining $\phi(x), \phi(y)$. Let $\lambda_{B2}$ denote $\Phi(\lambda_{el}) \times \{2\}$.

Fourthly, let $\Phi(\lambda)$ denote the hyperbolic geodesic joining $\phi(a), \phi(b)$. Let $\lambda_{B3}$ denote $\Phi(\lambda) \times \{3\}$.

For the universal cover $\tilde{B}$ of the thin block $B$, define:

$$B_{\lambda}(B) = \bigcup_{i=0, \ldots, 3} \lambda_{Bi}$$

**Definition:** Each $\tilde{S} \times i$ for $i = 0 \cdots 3$ will be called a horizontal sheet of $\tilde{B}$ when $B$ is a thick block.

Construction of $\Pi_{\lambda,B}$ - Thick Block

On $\tilde{S} \times \{0\}$, let $\Pi_{B0}$ denote nearest point projection onto $\lambda_{B0}$ in the path metric on $\tilde{S} \times \{0\}$.

28
On $\tilde{S} \times \{1\}$, let $\Pi_{B_1}$ denote nearest point projection onto $\lambda_{B_1}$ in the path metric on $\tilde{S} \times \{1\}$.

For the universal cover $\tilde{B}$ of the thick block $B$, define:

$$\Pi_{\lambda,B}(x) = \Pi_{B_i}(x), \quad x \in \tilde{S} \times \{i\}, \quad i = 0, 1$$

**Construction of $\Pi_{\lambda,B}$ - Thin Block**

On $\tilde{S} \times \{0\}$, let $\Pi_{B_0}$ denote nearest point projection onto $\lambda_{B_0}$. Here the nearest point projection is taken in the path metric on $\tilde{S} \times \{0\}$ which is a hyperbolic metric space.

On $\tilde{S} \times \{1\}$, let $\Pi_{B_1}$ denote the nearest point projection onto $\lambda_{B_1}$. Here the nearest point projection is taken in the sense of the definition preceding Lemma 3.16, that is minimizing the ordered pair $(d_{el}, d_{hyp})$ (where $d_{el}, d_{hyp}$ refer to electric and hyperbolic metrics respectively).

On $\tilde{S} \times \{2\}$, let $\Pi_{B_2}$ denote the nearest point projection onto $\lambda_{B_2}$. Here, again the nearest point projection is taken in the sense of the definition preceding Lemma 3.16.

Again, on $\tilde{S} \times \{3\}$, let $\Pi_{B_3}$ denote nearest point projection onto $\lambda_{B_3}$. Here the nearest point projection is taken in the path metric on $\tilde{S} \times \{3\}$ which is a hyperbolic metric space.

For the universal cover $\tilde{B}$ of the thin block $B$, define:

$$\Pi_{\lambda,B}(x) = \Pi_{B_i}(x), \quad x \in \tilde{S} \times \{i\}, \quad i = 0, \cdots, 3$$

**$\Pi_{\lambda,B}$ is a retract - Thick Block**

The proof for a thick block is exactly as in [23]. The crucial tool is Lemma 3.15.

**Lemma 4.1** There exists $C > 0$ such that the following holds:

Let $x, y \in \tilde{S} \times \{0, 1\} \subset B$ for some thick block $B$. Then $d(\Pi_{\lambda,B}(x), \Pi_{\lambda,B}(y)) \leq Cd(x, y)$.

**Proof:** It is enough to show this for the two following cases:

1. $x, y \in \tilde{S} \times \{0\}$ OR $x, y \in \tilde{S} \times \{1\}$.
2. $x, y$ are of the form $(p, 0)$ and $(\phi(p), 1)$ which are connected by a vertical segment of length one (as per the construction of the model $B$).
Case 1 above follows from Lemma 3.14, and Case 2 from the fact that \( \phi \) is a uniform quasi-isometry (depending on the uniform bound on the length of the Teichmüller geodesic over which \( B \) is the universal curve) and Lemma 3.15 which says that there exists \( C_1 > 0 \) such that if \( \pi \) be the nearest point retraction in \( \bar{S} \) onto \( \lambda \) then

\[
d(\phi(\pi(p)), \pi(\phi(p))) \leq C_1
\]

From this it follows that

\[
d(\Pi_{\lambda, B}((p, 0)), \Pi_{\lambda, B}((\phi(p), 1))) \leq C_1 + 1
\]

Choosing \( C = C_1 + 1 \) we are through. \( \square \)

\( \Pi_{\lambda, B} \) is a retract - Thin Block

The two main ingredients in this case are Lemmas 3.15 and 3.16.

Note: In the Lemma 4.2 below, there is implicit a constant \( n \), the twist coefficient of the Dehn twist that distinguishes \( B \). But the constant \( C \) below is independent of \( n \) due to the fact that powers of Dehn twists are uniform quasi-isometries of the electric metric. In fact this is the reason why we introduce the electric metric in the first place, so as to ensure that the techniques of [23] and [22] go through here.

**Lemma 4.2** There exists \( C > 0 \) such that the following holds:

Let \( x, y \in \bar{S} \times \{0, 1, 2, 3\} \subset B \) for some thin block \( B \). Then \( d_e(\Pi_{\lambda, B}(x), \Pi_{\lambda, B}(y)) \leq C d_e(x, y) \).

**Proof:** It is enough to show this for the two following cases:

1. \( x, y \in \bar{S} \times \{0\} \) OR \( x, y \in \bar{S} \times \{1\} \).

2. \( x = (p, 0) \) and \( y = (p, 1) \) for some \( p \)

3. \( x, y \) are of the form \( (p, 1) \) and \( (\phi(p), 2) \) which are connected by a vertical segment of length one (as per the construction of the model \( B \))
4. $x = (p, 2)$ and $y = (p, 3)$ for some $p$.

**Case 1:** As in Lemma 4.1 above, this follows from 3.14.

**Case 2 and Case 4:** These follow from Lemma 3.16 which says that the hyperbolic and electric projections of $p$ onto the hyperbolic geodesic $[a, b]$ and the electro-ambient geodesic $[a, b]_e$ respectively ‘almost agree’. If $\pi_h$ and $\pi_e$ denote the hyperbolic and electric projections, then there exists $C_1 > 0$ such that

$$d(\pi_h(p), \pi_e(p)) \leq C_1$$

Hence

$$d(\Pi_{\lambda, B}((p, i)), \Pi_{\lambda, B}((p, i + 1))) \leq C_1 + 1, \text{ for } i = 0, 2.$$

**Case 3:** First, from Lemma 3.13 the (power of the) Dehn twist $\phi$ used in the construction of $B$ is a (uniform) quasi-isometry of $\tilde{S}$ equipped with the electric metric. Again, if $\pi$ denotes the nearest point projection in the electric metric, then from Lemma 3.15, there exists $C_2 > 0$ such that

$$d_e(\phi(\pi(p)), \pi(\phi(p))) \leq C_2$$

Here $d_e$ denotes the electric metric. From this it follows that

$$d_e(\Pi_{\lambda, B}((p, 1)), \Pi_{\lambda, B}((\phi(p), 2))) \leq C_1 + 1$$

Choosing $C = \max(C_1 + 1, C_2 + 1)$ we are through. □

### 4.3 Modifications for Surfaces With Punctures

We deal with the thin block first.

**Thin Block**

For $S^h$ a hyperbolic surface with punctures, let $S$ denote $S^h$ minus some neighborhood of the cusps. Then the construction of the model $B$ and hence the graph model of $\tilde{B}$ for a thin block $B$ goes through *mutatis mutandis* even with respect to notation. The construction of the quasi-convex set and the retraction are modified as follows:
λ will no longer be a hyperbolic geodesic but rather an ambient quasi-
geodesic in \( \tilde{S} \). The construction is taken from [24]. We start with a hy-
perbolic geodesic \( \lambda^h \) in \( S^h \). Fix a neighborhood of the cusps lifting to an
equivariant family of horoballs in the universal cover \( \mathbb{H}^2 = \tilde{S}^h \). Since \( \lambda^h \)
is a hyperbolic geodesic in \( S^h \) there are unique entry and exit points for
each horoball that \( \lambda^h \) meets and hence unique Euclidean geodesics joining
them on the corresponding horosphere. Replacing the segments of \( \lambda^h \) lying
inside \( Z \)-horoballs by the corresponding Euclidean geodesics, we obtain an
ambient quasigeodesic λ in \( \tilde{M}_0 \) by Theorem 3.6. See Figure below:

![Horo-ambient quasigeodesics](image)

**Figure 3: Horo-ambient quasigeodesics**

Ambient quasigeodesics obtained by this kind of a construction will be
termed **horo-ambient quasigeodesics** to distinguish them from **electro-
ambient quasigeodesics** defined earlier. Starting with a horo-ambient quasigi-
desic \( \lambda \subset \tilde{S} \), we can proceed as before to construct \( B_{\lambda,B}, \Pi_{\lambda,B} \) and prove
Lemma 4.2 above. In fact the statement and proof of this Lemma goes
through unchanged, with the only pro viso that for punctured surfaces, \( S \)
and \( S^h \) are not the same and that λ is a horo-ambient quasigeodesic in gen-
eral. (Note that if \( S \) has no punctures, a horo-ambient quasigeodesic is a
hyperbolic geodesic.)

**Thick Block**

Here \( B \) is obtained from the universal curve over a Teichmüller geodesic
by removing a neighborhood of the cusps. Again, \( S \) is obtained from \( S^h \)
by removing a neighborhood of the cusps. That the map \( \phi \) is a uniform
quasi-isometry is ensured by the fact that the corresponding copies of \( S^h \)
are a uniformly bounded Teichmüller distance from each other, and that if \( \phi \) denote a map between these copies of \( S^h \), one can ensure that \( \phi \) takes cusps to cusps.

The construction of the graph model for \( \tilde{B} \), the construction of \( B_{\lambda,B} \) and \( \Pi_{\lambda,B} \) also go through as before with the proviso that \( \lambda \) is a \textit{hor-ambient quasi-geodesic}. Lemma 4.1 goes through as before.

5 Construction of Quasiconvex Sets

5.1 Construction of \( B_{\lambda} \) and \( \Pi_{\lambda} \)

Given a manifold \( M \) of \( i \)-bounded geometry, we know that \( M \) is homeomorphic to \( S \times J \) for \( J = [0, \infty) \) or \((-\infty, \infty)\). By definition of \( i \)-bounded geometry, there exists a sequence \( I_i \) of intervals and blocks \( B_i \) where the metric on \( S \times I_i \) coincides with that on some building block \( B_i \). Denote:

\[ B_{\mu,B_i} = B_i \mu \]
\[ \Pi_{\mu,B_i} = \Pi_{i\mu} \]

Now for a block \( B = S \times I \) (thick or thin), a natural map \( \Phi_B \) may be defined taking \( \mu = B_{\mu,B} \cap \tilde{S} \times \{0\} \) to a geodesic \( B_{\mu,B} \cap \tilde{S} \times \{k\} = \Phi_B(\mu) \) where \( k = 1 \) or \( 3 \) according as \( B \) is thick or thin. Let the map \( \Phi_{B_i} \) be denoted as \( \Phi_i \) for \( i \geq 0 \). For \( i < 0 \) we shall modify this by defining \( \Phi_i \) to be the map that takes \( \mu = B_{\mu,B} \cap \tilde{S} \times \{k\} \) to a geodesic \( B_{\mu,B} \cap \tilde{S} \times \{0\} = \Phi_i(\mu) \) where \( k = 1 \) or \( 3 \) according as \( B \) is thick or thin.

We start with a reference block \( B_0 \) and a reference geodesic segment \( \lambda = \lambda_0 \) on the 'lower surface' \( \tilde{S} \times \{0\} \). Now inductively define:

\[ \lambda_{i+1} = \Phi_i(\lambda_i) \text{ for } i \geq 0 \]
\[ \lambda_{i-1} = \Phi_i(\lambda_i) \text{ for } i \leq 0 \]
\[ B_{i\lambda} = B_{\lambda}(B_i) \]
\[ \Pi_{i\lambda} = \Pi_{\lambda,B_i} \]
\[ B_{\lambda} = \bigcup_i B_{i\lambda} \]
\[ \Pi_{\lambda} = \bigcup_i \Pi_{i\lambda} \]

Recall that each \( \tilde{S} \times i \) for \( i = 0 \cdots K \) is called a \textit{horizontal sheet} of \( \tilde{B} \), where \( K = 1 \) or \( 3 \) according as \( B \) is thick or thin. We will restrict our attention to the union of the horizontal sheets \( \tilde{M}_H \) of \( \tilde{M} \) with the induced metric.

Clearly, \( B_{\lambda} \subset \tilde{M}_H \subset \tilde{M} \), and \( \Pi_{\lambda} \) is defined from \( \tilde{M}_H \) to \( B_{\lambda} \). Since \( \tilde{M}_H \) is a 'coarse net' in \( \tilde{M} \), we will be able to get all the coarse information we
need by restricting ourselves to $\tilde{M}_H$.

By Lemmas 4.1 and 4.2, we obtain the fact that each $\Pi_{i\lambda}$ is a retract. Hence assembling all these retracts together, we have the following basic theorem:

**Theorem 5.1** There exists $C > 0$ such that for any geodesic $\lambda = \lambda_0 \subset \tilde{S} \times \{0\} \subset B_0$, the retraction $\Pi_{\lambda} : \tilde{M}_H \to B_\lambda$ satisfies:

$$\text{Then } d(\Pi_{\lambda,B}(x), \Pi_{\lambda,B}(y)) \leq Cd(x, y) + C.$$  

**NOTE 1** For Theorem 5.1 above, note that all that we really require is that the universal cover $\tilde{S}$ be a hyperbolic metric space. There is no restriction on $\tilde{M}_H$. In fact, Theorem 5.1 would hold for general stacks of hyperbolic metric spaces with hyperbolic Dehn surgery performed on blocks.

**Note 2:** $M_H$ has been given built up out of graph models of thick and thin blocks and have sheets that are electrocuted.

### 5.2 Heights of Blocks

Instead of considering all the horizontal sheets, we would now like to consider only the boundary horizontal sheets, i.e. for a thick block we consider $\tilde{S} \times \{0, 1\}$ and for a thin block we consider $\tilde{S} \times \{0, 3\}$. The union of all boundary horizontal sheets will be denoted by $\tilde{M}_{BH}$.

**Observation 1:** $\tilde{M}_{BH}$ is a ‘coarse net’ in $\tilde{M}$ in the graph model, but not in the model of i-bounded geometry.

In the graph model, any point can be connected by a vertical segment of length $\leq 2$ to one of the boundary horizontal sheets.

However, in the model of i-bounded geometry, there are points within Margulis tubes (say for instance, the center of the totally geodesic disk bounded by a meridian) which are at a distance of the order of $ln(n_i)$ from the boundary horizontal sheets. Since $n_i$ is arbitrary, $\tilde{M}_{BH}$ is no longer a ‘coarse net’ in $\tilde{M}$ equipped with the model of i-bounded geometry.

**Observation 2:** $\tilde{M}_H$ is defined only in the graph model, but not in the model of i-bounded geometry.

**Observation 3:** The electric metric on the model of i-bounded geometry on $\tilde{M}$ obtained by electrocuting all lifts of Margulis tubes is quasi-isometric to the graph model of $\tilde{M}$.

This follows from the fact that any lift of a Margulis tube has diameter 1 in the graph model of $\tilde{M}$.
Bounded Height of Thick Block

Let \( \mu \subset \tilde{S} \times \{0\} \overline{B_i} \) be a geodesic in a (thick or thin) block. Then there exists a \((K_i, \epsilon_i)\)-quasi-isometry \( \psi_i \) (\( = \phi_i \) for thick blocks) from \( \tilde{S} \times \{0\} \) to \( \tilde{S} \times \{1\} \) and \( \Psi_i \) is the induced map on geodesics. Hence, for any \( x \in \mu \), \( \psi_i(x) \) lies within some bounded distance \( C_i \) of \( \Psi_i(\mu) \). But \( x \) is connected to \( \psi_i(x) \) by

**Case 1 - Thick Blocks:** a vertical segment of length 1
**Case 2 - Thin Blocks:** the union of

1. two vertical segments of length 1 between \( \tilde{S} \times \{i\} \) and \( \tilde{S} \times \{i+1\} \) for \( i = 0, 2 \)

2. a horizontal segment of length bounded by (some uniform) \( C' \) (cf. Lemma 3.7) connecting \((x, 1)\) to a point on the electro-ambient geodesic \( B_\lambda(B) \cap \tilde{S} \times \{1\} \)

3. a vertical segment of length one in the graph model connecting \((x, 1)\) to \((\phi(x), 2)\). Such a path has to travel through the Margulis tube in the model of i-bounded geometry and has length less than \( g_0(n_i) \) for some function \( g_0 : \mathbb{Z} \to \mathbb{N} \), and \( n_i \) the twist coefficient.

4. a horizontal segment of length less than \( C' \) (Lemma 3.7) connecting \((\phi_i(x), 3)\) to a point on the hyperbolic geodesic \( B_\lambda(B) \cap \tilde{S} \times \{3\} \)

Thus \( x \) can be connected to a point on \( x' \in \Psi_i(\mu) \) by a path of length less than \( g(i) = 2 + 2C' + g_0(n_i) \). Here, in fact \( g_0 \) is at most linear in \( n_i \) but we shall not need this. Recall that \( \lambda_i \) is the geodesic on the lower horizontal surface of the block \( \overline{B_i} \). The same can be done for blocks \( \overline{B_{i-1}} \) and going down from \( \lambda_i \) to \( \lambda_{i-1} \). What we have thus shown is:

**Lemma 5.2** There exists a function \( g : \mathbb{Z} \to \mathbb{N} \) such that for any block \( B_i \) (resp. \( B_{i-1} \)), and \( x \in \lambda_i \), there exists \( x' \in \lambda_{i+1} \) (resp. \( \lambda_{i-1} \)) for \( i \geq 0 \) (resp. \( i \leq 0 \), satisfying:

\[
d(x, x') \leq g(i)
\]
Modifications for Punctured Surfaces

For a punctured surface, the above argument has to be modified using
some constructions from Lemma 5.1 of [24].

Given \( \lambda^h \in \widetilde{S}^h \) we have already indicated how to construct a
hor-ambient quasigeodesic \( \lambda \) in \( \widetilde{S} \) (where, recall that \( S \) is \( S^h \) minus a neighbor-
hood of cusps). Let \( \lambda_c \) denote the union of the segments of \( \lambda \) that lie along
cusps. Let \( \lambda_b = \lambda - \lambda_c \). For punctured surfaces, recall that \( \lambda_i \) is a hor-
ambient quasigeodesic on the lower horizontal surface of \( B_i \). \( \lambda_{ic} \) will denote
the union of segments of \( \lambda_i \) lying along cusps and \( \lambda_{ib} \) will denote \( \lambda_i - \lambda_{ic} \).

Lemma 5.1 of [24] says that there exists \( C_0 \) such that for any thick block
\( B_i \), and \( x \in \lambda_{ib} \) there exists \( x' \in \lambda_{i+1,b} \) such that \( d(x, x') \leq C' \). Combining
this with the argument given above for surfaces without punctures, we
conclude,

**Lemma 5.3** There exists a function \( g : \mathbb{Z} \to \mathbb{N} \) such that for any block \( B_i \)
(resp. \( B_{i-1} \)) and \( x \in \lambda_{ib} \), there exists \( x' \in \lambda_{i+1,b} \) (resp. \( \lambda_{i-1,b} \)) for \( i \geq 0 \)
(resp. \( i \leq 0 \)), satisfying:

\[
d(x, x') \leq g(i)
\]

**Note:** For a surface without punctures, \( \lambda \) and \( \lambda_b \) coincide.

6 Cannon-Thurston Maps for Surfaces Without Punctures

Unless explicitly mentioned otherwise, we shall assume till the end of this
section that

1. \( S \) is a closed surface. Hence \( S^h = S \).
2. there exists a hyperbolic manifold \( M \) and a homeomorphism from \( \overline{M} \)
to \( \widetilde{S} \times \mathbb{R} \). We identify \( \overline{M} \) with \( \widetilde{S} \times \mathbb{R} \) via this homeomorphism.
3. \( \widetilde{S} \times \mathbb{R} \) admits a quasi-isometry \( g \) to a model manifold of \textit{i-bounded geometry}
4. \( g \) preserves the fibers over \( \mathbb{Z} \subset \mathbb{R} \)
Remarks: 1) The above assumption is much stronger than what we need. It suffices to assume that $\tilde{M}$ is a Gromov-hyperbolic metric space. Further relaxations on the hypothesis may be considered while generalising the results of this paper to other hyperbolic metric spaces.

2) We have taken $J$ to be $\mathbb{R}$ here for concreteness. The other possibility of $J = \mathbb{R}^+$ can be treated in exactly the same way.

We shall henceforth ignore the quasi-isometry $g$ and think of $\tilde{M}$ itself as the universal cover of a model manifold of $i$-bounded geometry.

6.1 Admissible Paths

We want to define a collection of $B_\lambda$-elementary admissible paths lying in a bounded neighborhood of $B_\lambda$. $B_\lambda$ is not connected. Hence, it does not make much sense to speak of the path-metric on $B_\lambda$. To remedy this we introduce a ‘thickening’ (cf. [11]) of $B_\lambda$ which is path-connected and where the paths are controlled. A $B_\lambda$-admissible path will be a composition of $B_\lambda$-elementary admissible paths.

Recall that admissible paths in the graph model of bounded geometry consist of the following:

1. Horizontal segments along some $\tilde{S} \times \{i\}$ for $i = \{0, 1, 2, 3\}$ (thin blocks) or $i = \{0, 1\}$ (thick blocks).

2. Vertical segments $x \times [0, 1]$ or $x \times [2, 3]$ for thin blocks, where $x \in \tilde{S}$.

3. Vertical segments of length 1 joining $x \times \{1\}$ to $\phi(x) \times \{2\}$ for thin blocks.

4. Vertical segments of length 1 joining $x \times \{0\}$ to $\phi(x) \times \{1\}$ (or $x \times \{1\}$ if $\phi$ is regarded as the identity map at the topological level) for thick blocks.

We shall choose a subclass of these admissible paths to define $B_\lambda$-elementary admissible paths.

$B_\lambda$-elementary admissible paths in the thick block

Let $B = S \times [i, i+1]$ be a thick block, where each $(x, i)$ is connected by a vertical segment of length 1 to $(\phi(x), i+1)$. Also $\Phi$ is the map on geodesics induced by $\phi$. Let $B_\lambda \cap B = \lambda_i \cup \lambda_{i+1}$ where $\lambda_i$ lies on $\tilde{S} \times \{i\}$ and $\lambda_{i+1}$ lies on $\tilde{S} \times \{i+1\}$. $\pi_j$, for $j = i, i+1$ denote nearest-point projections of $\tilde{S} \times \{j\}$ onto $\lambda_j$. Next, since $\phi$ is a quasi-isometry, there exists $C > 0$ such
that for all $(x, i) \in \lambda_i$, $(\phi(x), i + 1)$ lies in a $C$-neighborhood of $\Phi(\lambda_i) = \lambda_{i+1}$. The same holds for $\phi^{-1}$ and points in $\lambda_{i+1}$, where $\phi^{-1}$ denotes the quasi-isometric inverse of $\phi$ from $\bar{S} \times \{i + 1\}$ to $\bar{S} \times \{i\}$. The $B_\lambda$-elementary admissible paths in $\bar{B}$ consist of the following:

1. Horizontal geodesic subsegments of $\lambda_j$, $j = \{i, i + 1\}$.
2. Vertical segments of length 1 joining $x \times \{0\}$ to $\phi(x) \times \{1\}$.
3. Vertical segments of length 1 joining $y \times \{1\}$ to $\phi^{-1}(y) \times \{0\}$.
4. Horizontal geodesic segments lying in a $C$-neighborhood of $\lambda_j$, $j = i, i + 1$.

$B_\lambda$-elementary admissible paths in the thin block

Let $B = \bar{S} \times [i, i + 3]$ be a thin block, where each $(x, i + 1)$ is connected by a vertical segment of length 1 to $(\phi(x), i + 2)$. Also $\Phi$ is the map on canonical representatives of electric geodesics induced by $\phi$. Let $B_\lambda \cap B = \bigcup_{j=i, i+3} \lambda_j$ where $\lambda_j$ lies on $\bar{S} \times \{j\}$. $\pi_j$ denotes nearest-point projection of $\bar{S} \times \{j\}$ onto $\lambda_j$ (in the appropriate sense - hyperbolic for $j = i, i + 3$ and electric for $j = i + 1, i + 2$). Next, since $\phi$ is an electric isometry, but a hyperbolic quasi-isometry, there exists $C > 0$ (uniform constant) and $K = K(B)$ such that for all $(x, i) \in \lambda_i$, $(\phi(x), i + 1)$ lies in an (electric) $C$-neighborhood and a hyperbolic $K$-neighborhood of $\Phi(\lambda_{i+1}) = \lambda_{i+2}$. The same holds for $\phi^{-1}$ and points in $\lambda_{i+2}$, where $\phi^{-1}$ denotes the quasi-isometric inverse of $\phi$ from $\bar{S} \times \{i + 2\}$ to $\bar{S} \times \{i + 1\}$.

Again, since $\lambda_{i+1}$ and $\lambda_{i+2}$ are electro-ambient quasigeodesics, we further note that there exists $C > 0$ (assuming the same $C$ for convenience) such that for all $(x, i) \in \lambda_i$, $(x, i + 1)$ lies in a (hyperbolic) $C$-neighborhood of $\lambda_{i+1}$. Similarly for all $(x, i + 2) \in \lambda_{i+2}$, $(x, i + 3)$ lies in a (hyperbolic) $C$-neighborhood of $\lambda_{i+3}$. The same holds if we go ‘down’ from $\lambda_{i+1}$ to $\lambda_i$ or from $\lambda_{i+3}$ to $\lambda_{i+2}$. The $B_\lambda$-elementary admissible paths in $B$ consist of the following:

1. Horizontal subsegments of $\lambda_j$, $j = \{i, \cdots i + 3\}$.
2. Vertical segments of length 1 joining $x \times \{i + 1\}$ to $\phi(x) \times \{i + 2\}$, for $x \in \lambda_{i+1}$.
3. Vertical segments of length 1 joining $x \times \{j\}$ to $x \times \{j + 1\}$, for $j = i, i + 2$. 

38
4. Horizontal geodesic segments lying in a hyperbolic $C$-neighborhood of $\lambda_j$, $j = i, \ldots, i + 3$.

5. Horizontal hyperbolic segments of electric length $\leq C$ and hyperbolic length $\leq K(B)$ joining points of the form $(\phi(x), i + 2)$ to a point on $\lambda_{i+2}$ for $(x, i + 1) \in \lambda_{i+1}$.

6. Horizontal hyperbolic segments of electric length $\leq C$ and hyperbolic length $\leq K(B)$ joining points of the form $(\phi^{-1}(x), i + 1)$ to a point on $\lambda_{i+1}$ for $(x, i + 2) \in \lambda_{i+2}$.

7. Hyperbolic geodesic segments lying entirely within some lift of a Margulis tube $N_k(\hat{\sigma}) \times [1, 2]$ joining points $x, y \in \lambda_{i+1} \cup \lambda_{i+2}$.

**Definition:** A $B_\lambda$-admissible path is a union of $B_\lambda$-elementary admissible paths.

The following lemma follows from the above definition and Lemma 5.2.

**Lemma 6.1** There exists a function $g : \mathbb{Z} \rightarrow \mathbb{N}$ such that for any block $B_i$, and $x$ lying on a $B_\lambda$-admissible path in $B_i$, there exist $y \in \lambda_j$ and $z \in \lambda_k$ where $\lambda_j \subset B_\lambda$ and $\lambda_k \subset B_\lambda$ lie on the two boundary horizontal sheets, satisfying:

$$d(x, y) \leq g(i)$$
$$d(x, z) \leq g(i)$$

Let $h(i) = \sum_{j=0}^{i} g(j)$ be the sum of the values of $g(j)$ as $j$ ranges from 0 to $i$ (with the assumption that increments are by +1 for $i \geq 0$ and by -1 for $i \leq 0$). Then we have from Lemma 6.1 above,

**Corollary 6.2** There exists a function $h : \mathbb{Z} \rightarrow \mathbb{N}$ such that for any block $B_i$, and $x$ lying on a $B_\lambda$-admissible path in $B_i$, there exist $y \in \lambda_0 = \lambda$ such that:

$$d(x, y) \leq h(i)$$

**Important Note:** In the above Lemma 6.1 and Corollary 6.2, it is important to note that the distance $d$ is **hyperbolic**, not electric. This is because the number $K(B_i)$ occurring in elementary paths of type 5 and 6 is a hyperbolic length depending only on $i$ (in $B_i$).
Next suppose that $\lambda$ lies outside $B_N(p)$, the $N$-ball about a fixed reference point $p$ on the boundary horizontal surface $\bar{S} \times \{0\} \subset \bar{B}_0$. Then by Corollary 6.2, any $x$ lying on a $B_\lambda$-admissible path in $B_i$ satisfies

$$d(x,p) \geq N - h(i)$$

Also, since the electric, and hence hyperbolic 'thickness' (the shortest distance between its boundary horizontal sheets) is $\geq 1$, we get,

$$d(x,p) \geq |i|$$

Assume for convenience that $i \geq 0$ (a similar argument works, reversing signs for $i < 0$). Then,

$$d(x,p) \geq \min\{i, N - h(i)\}$$

Let $h_1(i) = h(i) + i$. Then $h_1$ is a monotonically increasing function on the integers. If $h^{-1}_1(N)$ denote the largest positive integer $n$ such that $h(n) \leq m$, then clearly, $h^{-1}_1(N) \to \infty$ as $N \to \infty$. We have thus shown:

**Lemma 6.3** There exists a function $M(N) : \mathbb{N} \to \mathbb{N}$ such that $M(N) \to \infty$ as $N \to \infty$ for which the following holds: For any geodesic $\lambda \subset \bar{S} \times \{0\} \subset \bar{B}_0$, a fixed reference point $p \in \bar{S} \times \{0\} \subset \bar{B}_0$ and any $x$ on a $B_\lambda$-admissible path, $d(\lambda, p) \geq N \Rightarrow d(x, p) \geq M(N)$.

**Aside for Punctured Surfaces**

We mention parenthetically the versions of Corollary 6.2 and Lemma 6.3 here that will be useful for punctured surfaces in the next section.

**Corollary 6.4** There exists a function $h : \mathbb{Z} \to \mathbb{N}$ such that for any block $B_i$, and $x$ lying on $\lambda_{ib}$, there exist $y \in \lambda_{0b} = \lambda_b$ such that:

$$d(x, y) \leq h(i)$$

**Lemma 6.5** There exists a function $M(N) : \mathbb{N} \to \mathbb{N}$ such that $M(N) \to \infty$ as $N \to \infty$ for which the following holds:

For any horo-ambient quasigeodesic $\lambda \subset \bar{S} \times \{0\} \subset \bar{B}_0$, a fixed reference point $p \in \bar{S} \times \{0\} \subset \bar{B}_0$ and any $x$ on some $\lambda_{ib}$,
\[ d(\lambda_b, p) \geq N \Rightarrow d(x, p) \geq M(N). \]

In Lemma 6.5 we have used \( \lambda_b \) in place of \( \lambda \) as \( \lambda_b \) is constructed from \( \lambda^h \) by changing it along horocycles. However, another version of the above Lemma will also sometimes be useful. If we start with a \( \lambda^h \) that lies outside large balls about \( p \), we can ensure that \( \lambda_b \) also lies outside large balls about \( p \), for \( \lambda \) may approach \( p \) only along cusps. Hence we may replace the hypothesis that \( \lambda_b \) lie outside \( B_N(p) \) by the hypothesis that \( \lambda^h \) lie outside \( B_N(p) \):

**Lemma 6.6** There exists a function \( M(N) : \mathbb{N} \to \mathbb{N} \) such that \( M(N) \to \infty \) as \( N \to \infty \) for which the following holds:

For any hyperbolic geodesic \( \lambda^h \subset \tilde{S}^h \times \{0\} \subset \tilde{B}_0 \), a fixed reference point \( p \in \tilde{S}^h \times \{0\} \subset \tilde{B}_0 \) and any \( x \) on some \( \lambda_b \),

\[ d(\lambda^h, p) \geq N \Rightarrow d(x, p) \geq M(N). \]

### 6.2 Joining the Dots

Recall that **admissible paths** in a model manifold of bounded geometry consist of:

1. Horizontal segments along some \( \tilde{S} \times \{i\} \) for \( i = \{0, 1, 2, 3\} \) (thin blocks) or \( i = \{0, 1\} \) (thick blocks).

2. Vertical segments \( x \times [0, 1] \) or \( x \times [2, 3] \) for thin blocks.

3. Vertical segments of length 1 joining \( x \times \{1\} \) to \( \phi(x) \times \{2\} \) for thin blocks.

4. Vertical segments of length 1 joining \( x \times \{0\} \) to \( \phi(x) \times \{1\} \) for thick blocks.

Our strategy in this subsection is:

- **1** Start with an electric geodesic \( \beta_e \) in \( \tilde{M}_{el} \) joining the end-points of \( \lambda \).
- **2** Replace it by an **admissible quasigeodesic**, i.e. an admissible path that is
a quasigeodesic.

- Project the intersection of the admissible quasigeodesic with the horizontal sheets onto \( B_\lambda \).
- The result of step 3 above is disconnected. Join the dots using \( B_\lambda \)-admissible paths.

The end product is an electric quasigeodesic built up of \( B_\lambda \) admissible paths.

Now for the first two steps: Since \( \tilde{B} \) (for a thick block \( B \)) has thickness 1, any path lying in a thick block can be perturbed to an admissible path lying in \( \tilde{B} \), changing the length by at most a bounded multiplicative factor. For \( B \) thin, we decompose paths into horizontal paths lying in some \( \tilde{S} \times \{ j \} \), for \( j = 0, \cdots , 3 \) and vertical paths of types (2) or (3) above. All this can be done as for thick blocks, changing lengths by a bounded multiplicative constant. The result is therefore an electric quasigeodesic. Without loss of generality, we can assume that the electric quasigeodesic is one without back-tracking (as this can be done without increasing the length of the geodesic - see [8] or [13] for instance). Abusing notation slightly, assume therefore that \( \beta_r \) is a quasigeodesic without backtracking joining the end-points of \( \lambda \).

Now act on \( \beta_r \) by \( \Pi_\lambda \). From Theorem 5.1, we conclude, by restricting \( \Pi_\lambda \) to the horizontal sheets of \( \tilde{M}_\ell \) that the image \( \Pi_\lambda (\beta_r) \) is a 'dotted electric quasigeodesic' lying entirely on \( B_\lambda \). This completes step 3. Note that since \( \beta_r \) consists of admissible segments, we can arrange so that two nearest points on \( \beta_r \) which are not connected to each other are at a distance of one apart, i.e. they form the end-points of a vertical segment of type (2), (3) or (4).

Let \( \Pi_\lambda (\beta_r) \cap B_\lambda = \beta_d \), be the dotted quasigeodesic lying on \( B_\lambda \). We want to join the dots in \( \beta_d \) converting it into a connected electric quasigeodesic built up of \( B_\lambda \)-admissible paths.

For vertical segments of type (4) joining \( p, q \) (say), \( \Pi_\lambda (p), \Pi_\lambda (q) \) are a bounded hyperbolic distance apart. Hence, by the proof of Lemma 4.1, we can join \( \Pi_\lambda (p), \Pi_\lambda (q) \) by a \( B_\lambda \)-admissible path of length bounded by some \( C_0 \) (independent of \( B, \lambda \)).

For vertical segments of type (2) joining \( p, q \), we note that \( \Pi_\lambda (p), \Pi_\lambda (q) \) are a bounded hyperbolic distance apart. Hence, by the proof of Lemma 4.2, we can join \( \Pi_\lambda (p), \Pi_\lambda (q) \) by a \( B_\lambda \)-admissible path of length bounded by some \( C_1 \) (independent of \( B, \lambda \)).

This leaves us to deal with case (3). Such a segment consists of a segment lying within a lift of a Margulis tube and a horizontal segment of length 1.
lying outside. Decompose the bit within a Margulis tube into a horizontal segment lying on some horizontal surface and (possibly) a vertical segment of hyperbolic length 1. The image of the horizontal part of the path is again uniformly bounded in the electric metric. Further, by co-boundedness, we can ensure that the hyperbolic length of the image away from the lift of at most one Margulis tube lying in the zero neighborhood of $B_\lambda$ is bounded uniformly by some $C_2$. The same can be ensured of vertical paths of hyperbolic length one lying inside lifts of Margulis tubes. These two pieces (images under $\Pi_\lambda$ of horizontal paths inside lifts of Margulis tubes and vertical segments of length one inside lifts of Margulis tubes) can be replaced by $B_\lambda$-admissible paths of uniformly bounded electric length (since at most one lift of a Margulis tube lying in a zero neighborhood of $B_\lambda$ is in the image for length $\geq C_2$.) Finally, the segment lying outside, being horizontal, its image is connected and of bounded length by Lemma 3.14.

After joining the dots, we can assume further that the quasigeodesic thus obtained does not backtrack (cf [8] and [13]).

Putting all this together, we conclude:

**Lemma 6.7** There exists a function $M(N) : \mathbb{N} \to \mathbb{N}$ such that $M(N) \to \infty$ as $N \to \infty$ for which the following holds:

For any geodesic $\lambda \subset \bar{S} \times \{0\} \subset B_0$, and a fixed reference point $p \in \bar{S} \times \{0\} \subset B_0$, there exists a connected electric quasigeodesic $\beta_{adm}$ without backtracking, such that

- $\beta_{adm}$ is built up of $B_\lambda$-admissible paths.
- $\beta_{adm}$ joins the end-points of $\lambda$.
- $d(\lambda, p) \geq N \Rightarrow d(\beta_{adm}, p) \geq M(N)$.

**Proof:** The first two criteria follow from the discussion preceding this lemma. The last follows from Lemma 6.3 since the discussion above gives a quasigeodesic built up out of admissible paths. \(\square\)

### 6.3 Proof of Theorem

**Electric Geometry Revisited**

We note the following properties of the pair $(X, \mathcal{H})$ where $X = \bar{M}$ and $\mathcal{H}$ consists of the lifts of Margulis tubes in $M$ to the universal cover. Each lift of a Margulis tube shall henceforth be termed an extended Margulis tube. There exist $C, D, \Delta$ such that

43
1. Each extended Margulis tube is $C$-quasiconvex.

2. Any two extended Margulis tubes are $D$-separated.

3. The collection $\mathcal{H}$ is $C$-cobounded, i.e. the nearest point projection of any member of $\mathcal{H}$ onto any other has diameter bounded by $C$.

4. $\tilde{M}_{el} = X_{el}$ is $\Delta$-hyperbolic, (where $\tilde{M}_{el} = X_{el}$ is the electric metric on $M = X$ obtained by electrocuting all extended Margulis tubes, i.e. all members of $\mathcal{H}$).

5. $(X_{el}, \mathcal{H})$ has the Bounded Penetration Property.

6. An electro-ambient quasigeodesic is a hyperbolic quasigeodesic.

The first property follows from the fact that each $\epsilon$-neighborhood of a closed geodesic in a hyperbolic manifold is convex for sufficiently small $\epsilon$.

The second follows from choosing $\epsilon$ sufficiently small.

The third follows from the uniform separation of (the convex) extended Margulis sets.

The fourth and fifth follow from Lemmas 3.3 and 3.4.

Property (6) follows from Lemma 3.9.

Note: So far we have not used the hypothesis that $\tilde{M}$ and hence, (from Property (4) above, or by Lemma 3.3) $\tilde{M}_{el}$ are hyperbolic metric spaces. It is at this stage that we shall do so and assemble the proof of the main Theorem.

**Theorem 6.8** Let $M$ be a 3 manifold homeomorphic to $S \times J$ (for $J = [0, \infty)$ or $(-\infty, \infty)$). Further suppose that $M$ has i-bounded geometry, where $S_0 \subset B_0$ is the lower horizontal surface of the building block $B_0$. Then the inclusion $i : \tilde{S} \to M$ extends continuously to a map $i : \tilde{S} \to \tilde{M}$. Hence the limit set of $\tilde{S}$ is locally connected.

**Proof:** Suppose $\lambda \subset \tilde{S}$ lies outside a large $N$-ball about $p$. By Lemma 6.7 we obtain an electric quasigeodesic without backtracking $\beta_{adm}$ built up of $B_\lambda$-admissible paths lying outside an $M(N)$-ball about $p$ (where $M(N) \to \infty$ as $N \to \infty$).

Suppose that $\beta_{adm}$ is a $(K, \epsilon)$ quasigeodesic. Note that $K, \epsilon$ depend on ‘the Lipschitz constant’ of $\Pi_\lambda$ and hence only on $\tilde{S}$ and $\tilde{M}$.

From Property (6) (or Lemma 3.8) we find that if $\beta^h$ denote the hyperbolic geodesic in $M$ joining the end-points of $\lambda$, then $\beta^h$ lies in a (uniform) $C'$ neighborhood of $\beta_{adm}$.

44
Let \( M_1(N) = M(N) - C' \). Then \( M_1(N) \to \infty \) as \( N \to \infty \). Further, the hyperbolic geodesic \( \beta^h \) lies outside an \( M_1(N) \)-ball around \( p \). Hence, by Lemma 2.1, the inclusion \( i : \hat{S} \to \hat{M} \) extends continuously to a map \( \hat{i} : \hat{S} \to \hat{M} \).

Since the continuous image of a compact locally connected set is locally connected (see [12]) and the (intrinsic) boundary of \( \hat{S} \) is a circle, we conclude that the limit set of \( \hat{S} \) is locally connected.

This proves the theorem. \( \square \)

7 Cannon-Thurston Maps for Surfaces With Punctures

7.1 Modification of Construction for Punctured Surfaces

We summarise the modifications to be made to the construction in the previous sections, so as to make the results applicable for punctured surfaces:

1. \( \lambda \) is now a horo-ambient quasigeodesic built out of a hyperbolic geodesic \( \lambda^h \)

2. \( \Pi_\lambda \) and \( B_\lambda \) are constructed as before

3. Let \( \beta_a \) be an ambient admissible quasigeodesic, i.e. an ambient quasi-geodesic built up of elementary admissible paths. Then \( \Pi_\lambda(\beta_a \cap \overline{M_{BH}}) \subset B_\lambda \).

4. Joining the dots on this projected image of \( \beta_a \), we obtain finally via Lemma 6.5
   - Suppose \( \lambda^h \) lies outside large balls about a fixed reference point \( p \).
     There exists an ambient admissible electric quasigeodesic \( \beta_{amb} \) in \( M_{el} \) such that any horizontal piece of \( \beta_{amb} \cap B_\lambda^h \) also lies outside large balls. Further, any piece of \( \beta_{amb} \) lying wholly inside the lift of a Margulis tube also lies outside large balls. (Note that \( B_\lambda^h = \bigcup_i \lambda_{ib} \)).

Next recall that \( M^h \) is a hyperbolic manifold with cusps, and that excising these cusps we get \( M \) which is naturally homeomorphic to \( S \times J \) where \( J = \mathbb{R} \) or \([0, \infty)\). Further we may assume that \( M \) is given the structure of a
model of i-bounded geometry. (Here we are abusing notation slightly as $M$, strictly speaking, is only quasi-isometric to a model of i-bounded geometry.) Let $M_h^h$, $M_{el}$ denote $M^h$, $M$ with Margulis tubes electrolyzed. Let $\mathcal{H}_0$ denote the collection of horoballs that correspond to the lifts of cusps in $\widetilde{M}_{el}^h$. Thus, $\widetilde{M}_{el} = \overline{M^h_{el}} - \{ H : H \in \mathcal{H}_0 \}$. $\tilde{M}_h^h$ is hyperbolic by Lemma 3.2.

Now let $\beta_{el}^h$ be the electric geodesic in the hyperbolic metric space $\widetilde{M}_h^h$ joining the end-points $a, b$ of $\lambda^h$. Let $H(\beta_{el}^h)$ denote the union of $\beta_{el}^h$ and the collection of horoballs in $\mathcal{H}_0$ that $\beta_{el}^h$ meets. Then by Theorem 3.6 (using the fact stated there that the theorem goes through for separated mutually cobounded uniformly quasiconvex sets), we have

1. $H(\beta_{el}^h)$ is quasiconvex in $\widetilde{M}_h^h$.
2. $\beta_{amb}$ lies in a bounded electric neighborhood of $H(\beta_{el}^h)$

7.2 Electrically close implies hyperbolically close

In what follows we want to construct out of $\beta_{amb}$ a hyperbolic quasigeodesic $\gamma$ in $\widetilde{M}_{el}^h$ such that entry and exit points of $\gamma$ with respect to $H \in \mathcal{H}_0$ lie outside large balls $B_N(p) \subset M$ (here the metric is the hyperbolic metric). The strategy is as follows:

For any $H \in \mathcal{H}_0$ look at the part $\beta_i$ of $\beta_{amb}$ that lies close to $H_i$. We claim that if this piece is long, then after pruning it a bit at the ends if necessary, the pruned subsegment of $\beta_i$ lies hyperbolically close to $H_i$. We make this precise below.

By Theorem 3.6, and as in [16], there exists $\Delta > 0$ such that $\beta_{amb}$ lies in an (electric) $\Delta$ neighborhood of $H(\beta_{el}^h)$. Let $H_1, \cdots, H_k$ denote the horoballs in $H(\beta_{el}^h)$. Let $\beta_i$ be the maximal subsegment of $\beta_{amb}$ joining points of $N_{\Delta}(H_i) \cap \beta_{amb}$. Then there exists $D = D(\Delta)$ such that $\beta_i \subset N_D^h(H_i)$. Let $a_i, b_i$ be the end-points of $\beta_i$ and $P_i$ denote nearest point projection onto $H_i$. $[x, y]_e$ will denote the electric geodesic joining $x, y$. $[P_i(x), P_i(y)]$ will denote the hyperbolic geodesic joining $P_i(x), P_i(y)$ within the horoball $H_i$.

Fixing $K \geq 0$ ($K = 4D$ will suffice for our purposes) let $a_i, d_i \in \beta_i$ be such that $c_i d_i$, the subsegment of $\beta_i$ joining $c_i, d_i$ has length less than $K$. Suppose further that $a_i, c_i, d_i, b_i$ occur in that order along the segment joining $a_i, b_i$. Then $[P_i(a_i), c_i] \cup c_i d_i \cup [d_i, P_i(d_i)] \cup [P_i(d_i), P_i(a_i)] = \sigma$ is a loop of electric length
less than \( C = C(K, D) \) (= \( C(D) \) if \( K = 4C \)). This follows from the following observations:
1) \( [P(c_i, c_i), [P(d_i, d_i)] \) have length less than or equal to \( D \)
2) \( c_i d_i \) has length less than \( K \)
3) \( [P_i(c_i), P_i(d_i)] \) has length bounded in terms of \( K \) by Lemma 3.14.

Since \( \sigma \) has electric length less than \( C \), we could conclude that \( \sigma \) has bounded hyperbolic length by Lemma 3.11 if in addition we knew that \( \sigma \) does not backtrack. (In particular we would be able to show that \( \sigma \) has bounded penetration.) However, we only know that each of the four components of \( \sigma \) individually does not backtrack. In fact, \( [c_i, P_i(c_i)] \cup [P_i(c_i), P_i(d_i)] \cup [P_i(d_i), d_i] \) is a path without backtracking. Therefore, backtracking, if it exists, is a consequence of overlap of initial segments of \( [c_i, P_i(c_i)] \) and \( c_i d_i \) (or, \( [d_i, P_i(d_i)] \) and \( d_i c_i \)). Clearly, such overlaps can have length at most \( D \). Therefore, any such segment \( c_i d_i \) with \( d_c(a_i, c_i) \geq D \), \( c_i d_i \geq D \) must have bounded penetration property (since the paths \( [a_i, P_i(a_i)] \cup [P_i(a_i), P_i(b_i)] \cup [P_i(b_i), b_i] \) and \( a_i b_i \) can have overlaps of length at most \( D \) at the beginning and end), i.e. there exists \( D_0 = D_0(D, K) \geq 0 \) such that \( c_i d_i \cap T \) has hyperbolic length less than \( D_0 \) (where \( T \) is any lift of a Margulis tube).

Now, choose \( x \in a_i b_i \) such that \( d_c(x, a_i) \geq 2D \) and \( d_c(x, b_i) \geq 2D \). Choose \( c_i, d_i \) such that \( d_c(x, c_i) = 2D \), \( d_c(x, d_i) = 2D \) and \( a_i, c_i, d_i, b_i \) lie in that order along the path from \( a_i \) to \( b_i \). Then using the loop \( [P_i(c_i), c_i] \cup c_i x \cup [x, P_i(x)] \cup [P_i(x), P_i(c_i)] = \sigma \) and the argument above, we conclude that \( [x, P(x)] \) satisfies the bounded penetration property and hence \( [x, P(x)] \) has bounded hyperbolic length. This is summarised in the following Lemma.

**Lemma 7.1** There exists \( D_0 \geq 0 \) such that the following holds. Let \( \beta_i = a_i b_i \) be as above and \( x \in a_i b_i \) such that \( d_c(x, a_i) \geq 2D \), \( d_c(x, b_i) \geq 2D \). Then \( d(x, H_i) \leq D_0 \). (Note that \( d(x, H_i) \) denotes hyperbolic distance.)

Thus the subpath of \( \beta_i \) obtained by pruning pieces of (electric) length \( 2D \) from the beginning and the end lies in a bounded hyperbolic neighborhood of \( H_i \) (and not just in a bounded electric neighborhood of \( H_i \)).

### 7.3 Constructing an electric quasigeodesic

The argument in this subsection is a slight modification of the argument in [24] for punctured surfaces of bounded geometry. The slight modifica-
tion is due to pruning electric quasigeodesics that follow a horoball for a considerable length.

Choose from the the collection of $H_i \in \mathcal{H}(\beta)$ the subcollection for which $\beta_i$ has diameter greater than $4D$. We denote this subcollection as $\mathcal{H}_i(\beta)$ (I stand for ‘large’). Let $H_i, \ldots, H_k$ be the horoballs in this collection.

For the relevant subpaths $\beta_{i1}, \ldots, \beta_{ik}$ of $\beta$ we construct $\gamma_{i1}, \ldots, \gamma_{ik}$ as follows.

Let $\alpha_{ii} = a_{ii}d_{ii} \subset \beta_{ii} = a_{ii}b_{ii}$ denote the subpath at distance less than or equal to $D$ from $H_i$. By Lemma 7.1 we have $d_e(c_{ii}, a_{ii}) \leq 2D$ and $d_e(d_{ii}, b_{ii}) \leq 2D$. Let

$$\gamma_{ii} = [c_{ii}, P_i(c_{ii})]_e \cup [P_i(c_{ii}), P_i(d_{ii})] \cup [P_i(d_{ii}), d_{ii}]_e$$

Let $\gamma = (\beta - \bigcup_i \beta_{ii}) \bigcup \bigcup_i \gamma_{ii}$.

Each $\beta_{ii}$ starts and ends (electrically) close to the entry and exit points $u_{ii}, v_{ii}$ of $\beta_{cl}$ with respect to the horoball $H_i$.

Since $c_{ii}, d_{ii}$ are close (bounded by $2D$) to $a_{ii}, b_{ii}$ respectively, then from Lemma 3.5, Lemma 3.11 and Lemma 3.14 we find that there exists $D_1 \geq 0$ such that

$$d(P_i(c_{ii}), P_i(a_{ii})) \leq D_1$$
$$d(P_i(d_{ii}), P_i(b_{ii})) \leq D_1$$

Note that $d$ here is the hyperbolic distance. Hence the hyperbolic geodesic $[c_{ii}, d_{ii}]$ lies close to $[a_{ii}, b_{ii}]$ and hence to the hyperbolic geodesic $[u_{ii}, v_{ii}]$ (by fellow traveller property).

Thus we conclude

$\gamma$ lies in a bounded neighbourhood of the electric geodesic $\beta_{cl}$.

**Note:** The remaining $\beta_i$’s being less than $4D$ in length are therefore uniformly bounded. Hence their projections onto the corresponding $H_i$’s are also uniformly bounded in diameter. The length of $\beta_{cl} \cap H_i$ for these $H_i$’s is also therefore uniformly bounded. (Else the projection onto $\beta_{cl} \cap \mathcal{H}(\beta_i)$ would have to have jumps and hence not be ‘large-scale continuous’.)

Since $\gamma$ is obtained from $\beta_{amb}$, $\gamma$ tracks $\beta_{cl}$ off horoballs. Further, since entry and exit points of $\gamma$ and $\beta_{cl}$ with respect to horoballs are a bounded distance apart, they are fellow travellers within horoballs. From this it follows easily that $\gamma$ is an electric quasigeodesic.

$\gamma$ therefore has two properties:

1. $\gamma$ lies close to $\beta_{cl}$ and is an electric quasigeodesic.
2. All points of $\gamma \cap \bar{M}$ lie outside a large ball about the fixed reference point $p$ if $\lambda^h$ does.

The first property follows from the above discussion and the last is just a restatement of property (4) of Section 7.1 (the first subsection of the present section), coupled with the fact that entry points of $\gamma$ into horoballs $H_i \in \mathcal{H}$ lie hyperbolically close to $\beta_{amb}$.

This gives rise to the following property of $\gamma$. Recall that building blocks are built from the truncated surface $\bar{S}$, and that we fix a 'starting block' $B_0$. We identify $\bar{S} \times \{0\}$ with the truncated surface obtained from $S^h$ the hyperbolic reference surface.

**Proposition 7.2** There exists a function $M(N) : \mathbb{N} \to \mathbb{N}$ such that $M(N) \to \infty$ as $N \to \infty$ for which the following holds:

For any geodesic $\lambda^h \subset S^h$, and a fixed reference point $p \in \bar{S} \times \{0\} \subset B_0$, there exists a connected electric quasigeodesic $\gamma$ without backtracking, such that

- If $\lambda^h$ lies outside $B_N(p)$, then every point $x$ of $\gamma - \{H : H \in \mathcal{H}\}$ lies at a hyperbolic distance of at least $M(N)$ from $p$.

The above Proposition is a punctured surface version of Lemma 6.7.

Now, recall a Lemma from [24] (which has been proven there as a part of Theorem 5.9).

**Lemma 7.3** There exists a function $M_1(N)$ such that $M_1(N) \to \infty$ as $N \to \infty$ satisfying the following:

Given a uniformly separated collection of horoballs $\mathcal{H}$ and a point $p$ lying outside them, let $\gamma$ be a path without backtracking, such that $\gamma - \{H : H \in \mathcal{H}\}$ lies outside $B_N(p)$. Further suppose that $\gamma \cap H$ is a (hyperbolic) geodesic, whenever $\gamma \cap H$ is non-empty. Then $\gamma$ lies outside an $M_1(N)$ ball about $p$.

Combining Proposition 7.2 (for pieces of $\gamma$ outside horoballs) and Lemma 7.3 above (for the geodesic segments within horoballs) we conclude:

**Proposition 7.4** There exists a function $M(N) : \mathbb{N} \to \mathbb{N}$ such that $M(N) \to \infty$ as $N \to \infty$ for which the following holds:

For any geodesic $\lambda^h \subset S^h$, and a fixed reference point $p \in \bar{S} \times \{0\} \subset B_0$,
there exists a connected electric quasigeodesic $\gamma$ without backtracking, such that

- If $\lambda^h$ lies outside $B_N(p)$, then every point $x$ of $\gamma$ lies at a hyperbolic distance of at least $M(N)$ from $p$.

### 7.4 From electric quasigeodesics to hyperbolic quasigeodesics

We have thus constructed an electric quasigeodesic $\gamma$ without backtracking joining the end-points of $\lambda^h$ every point of which lies outside a (hyperbolic) large ball about $p$. The last step is to promote $\gamma$ to a hyperbolic quasigeodesic.

Since $\gamma$ is built up of admissible paths within Margulis tubes, we might as well assume that $\gamma$ is an electro-ambient quasigeodesic without backtracking.

**Lemma 7.5** The underlying path of $\gamma$ is a hyperbolic quasigeodesic.

**Proof:** Margulis tubes satisfy the mutual co-boundedness property by Lemma 3.5. Hence by Lemma 3.9, $\gamma$ is a hyperbolic quasigeodesic. $\square$

**Theorem 7.6** Let $M^h$ be a 3 manifold homeomorphic to $S^h \times J$ (for $J = [0, \infty)$ or $(-\infty, \infty)$). Further suppose that $M^h$ has $i$-bounded geometry. Let $S_0 \subset B_0$ be the lower horizontal surface of the building block $B_0$ in the manifold $M$ obtained by removing cusps. Then the inclusion $i : \hat{S}^h \to \hat{M}^h$ extends continuously to a map $\hat{i} : \hat{S}^h \to \hat{M}^h$. Hence the limit set of $\hat{S}$ is locally connected.

**Proof:** Suppose $\lambda^h \subset \hat{S}^h$ lies outside a large $N$-ball about $p$. By Lemma 7.4 and Lemma 7.5, we obtain a hyperbolic quasigeodesic $\gamma$ lying outside an $M(N)$-ball about $p$ (where $M(N) \to \infty$ as $N \to \infty$).

If $\beta^h$ denote the hyperbolic geodesic in $\hat{M}^h$ joining the end-points of $\lambda^h$, then $\beta^h$ lies in a (uniform) $C'$ neighborhood of $\gamma$ (since hyperbolic quasigeodesics starting and ending at the same points track each other throughout their lengths).

Let $M_1(N) = M(N) - C'$. Then $M_1(N) \to \infty$ as $N \to \infty$. Further, the hyperbolic geodesic $\beta^h$ lies outside an $M_1(N)$-ball around $p$. Hence, by Lemma 2.1, the inclusion $\hat{i} : \hat{S}^h \to \hat{M}^h$ extends continuously to a map $\hat{i} : \hat{S}^h \to \hat{M}^h$.

Since the continuous image of a compact locally connected set is locally connected (see [12]) and the (intrinsic) boundary of $\hat{S}^h$ is a circle, we conclude that the limit set of $\hat{S}$ is locally connected.
This proves the theorem. □

The proof of the above theorem is just a modification of Theorem 6.8, once Lemma 7.4 and Lemma 7.5 are in place.

8 Cannon-Thurston Maps for Pared Manifolds

In this section, we combine the the methods of [24] with those of the last two sections to conclude:

**Theorem 8.1** Suppose that \( N^h \in H(M, P) \) is a hyperbolic structure of i-bounded geometry on a pared manifold \((M, P)\) with incompressible boundary \( \partial_0 M \). Let \( M_{gf} \) denote a geometrically finite hyperbolic structure adapted to \((M, P)\). Then the map \( i : \hat{M}_{gf} \to \hat{N}^h \) extends continuously to the boundary \( \hat{i} : \hat{M}_{gf} \to \hat{N}^h \). If \( \Lambda \) denotes the limit set of \( M \), then \( \Lambda \) is locally connected.

See [24] for definition of pared manifold with incompressible boundary (this coincides with the notion of manifolds whose boundary is incompressible away from cusps). Theorem 7.6 and its proof takes the place of Theorem 4.15 of [24]. Since nothing else is new, given these constituents, we content ourselves with giving an outline of the proof.

**Outline of Proof of Theorem 8.1**

**Step 1** Construct \( B_{\lambda} \) in \( \hat{M} \) (\( = \hat{M}^h \) - cusps) as in Section 4.1 of [24]. The only difference is that for an end \( E \) of i-bounded geometry, \( E \) is given the lectric metric after electrocuting lifts of Margulis tubes.

**Step 2** As in Sections 4.2, 4.3 of [24] we obtain a retract \( \Pi_{\lambda} \) onto \( B_{\lambda} \).

**Step 3** Construct a ‘dotted’ ambient electric quasigeodesic lying on \( B_{\lambda} \) by projecting some(ay) ambient electric quasigeodesic onto \( B_{\lambda} \) by \( \Pi_{\lambda} \).

**Step 4** Join the dots using admissible paths as in Section 6.2 (**Joining the Dots**) of this paper. This results in a connected ambient electric quasigeodesic \( \beta_{amb} \).

**Step 5** Construct from \( \beta_{amb} \subset \hat{M} \) an electric quasigeodesic \( \gamma \) in \( \hat{M}^h \) as in the previous section by replacing pieces of \( \beta_{amb} \) that lie close to horoballs by hyperbolic quasigeodesics that lie (apart from bounded length segments at the beginning and end) within horoballs.

**Step 6** Conclude that if \( \lambda^h \) lies outside large balls in \( S^h \) then each point of the path \( \gamma \) also lies outside large balls.

**Step 7** Since the underlying set of \( \gamma \) is a hyperbolic quasigeodesic by Lemma 3.9, and so must lie close to a hyperbolic geodesic \( \beta^h \) joining the end-points.
of $\lambda^h$, we conclude that $\beta^h$ lies outside large balls. Hence by Lemma 2.1 there exists a Cannon-Thurston map and the limit set is locally connected. **Step 8** As in [24], the Steps 1-7 above are carried out first for manifolds of $p$-incompressible boundary. Then in the last step (as in Section 5.4 of [24]) the hypothesis is relaxed and the result proven for pared manifolds with incompressible boundary. (Recall from [24] that p-incompressibility roughly means the absence of accidental parabolics in any hyperbolic structure.) Note also that the definition of pared manifolds with incompressible boundary coincides with the notion of ‘incompressibility away from cusps’ introduced by Brock, Canary and Minsky in [5].

Since punctured torus groups have $i$-bounded geometry by a theorem of Minsky [18], we obtain the following Theorem of McMullen [16] as a Corollary.

**Theorem 8.2** (McMullen [16]) Let $M^h$ be a hyperbolic 3 manifold homeomorphic to $S^h \times J$ (for $J = [0, \infty)$ or $(-\infty, \infty)$), where $S^h$ is a punctured torus. Let $i : S^h \rightarrow M^h$ be a type-preserving (i.e. taking parabolics to parabolics) homotopy equivalence. Then the inclusion $\tilde{i} : \tilde{S}^h \rightarrow \tilde{M}^h$ extends continuously to a map $\hat{i} : \hat{S}^h \rightarrow \hat{M}^h$. Hence the limit set of $S^h$ is locally connected.

In a subsequent paper [25], we extend the notion of $i$-bounded geometry step-by-step to include more general geometries and prove the Cannon-Thurston property for these geometries.
