C. P. Ramanujam

A Tribute
Preface

This collection of the publications of Chidambaram Padmanabhan Ramanujam and of the several papers, in his memory, by his friends and colleagues is intended to be a tribute to a distinguished colleague.

C.P. Ramanujam joined the School of Mathematics of the Tata Institute of Fundamental Research as a Research Student in 1957. In his meteoric career he had done brilliant work in Number Theory and Algebraic Geometry. He was, without doubt, one of the outstanding young Indian mathematicians of the last twenty years. Gifted with a remarkably deep and wide mathematical culture, he was at home as much with abstract Algebraic Geometry as with analytic methods of Number Theory. A conversation with him was a rewarding experience for students and colleagues alike. He passed away, in Bangalore, when he was hardly 37 years old.

I should like to thank all those who contributed papers to this volume, and in addition Jal R. Choksi, K. Gowrisankaran, Pavaman Murthy, Raghavan Narasimhan and K. Srinivasacharyulu for their assistance. I am also grateful to C.P. Rajagopal, brother of Ramanujam, for some biographical details concerning Ramanujam.

K.G. Ramanathan
Acknowledgements

The Editor and the Tata Institute of Fundamental Research wish to thank the following societies and publishers of Journals for kindly giving permission to reprint, in this volume, the papers of C.P. Ramanujam, as listed below:

*American Journal of Mathematics:* Johns Hopkins University Press, Baltimore  
(No. 7)

*Annals of Mathematics:* the Editors  
(No. 5)

*Journal of the Indian Mathematical Society:* the Editor  
(Nos. 4, 6, 9)

*Mathematika:* University College, London  
(No. 2)

*Mathematische Annalen and Inventiones Mathematicae:* Springer-Verlag, Heidelberg  
(Nos. 3, 8, 10)

*Proceedings of the Cambridge Philosophical Society:* Cambridge University Press  
(No. 1)

Publications of C.P. Ramanujam

1. Cubic forms over algebraic number fields :
   Proceedings of the Cambridge Philosophical Society, 59 (1963) 683-705 21

2. Sums of $m$-th powers in $p$-adic rings :
   Mathematika, 10 (1963), 137-146 59

3. A note on automorphism groups of algebraic varieties
   Mathematische Annalen, 156 (1964), 25-33 73

4. On a certain purity theorem :

5. A topological characterisation of the affine plane as an algebraic variety :
   Annals of Mathematics, 94 (1971), 69-88 97

6. Remarks on the Kodaira Vanishing Theorem :
   Journal of the Indian Mathematical Society, 36 (1972), 41-51 123

7. The invariance of Milnor’s number implies the invariance of the topological type (jointly with Le Dung Trang)
   American Journal of Mathematics, 98 (1976), 67-78 135
8. On a geometric interpretation of multiplicity: 
   *Inventiones Mathematicae*, 22 (1973), 63-67

9. Supplement to the article “Remarks on the Kodaira Vanishing Theorem”:

10. Appendix to the paper of C.S. Seshadri entitled “Quotient space by an abelian variety”:
    *Mathematische Annalen*, 152 (1963), 192-194

11. The theorem of Tate, Appendix I to the book entitled “Abelian Varieties” by D. Mumford

**Contributed papers:**

B. TEISSIER: On a Minkowski-type inequality for multiplicities—II 407
Chidambaram Padmanabhan Ramanujam was born in Madras on January 9, 1938, as the eldest son of Shri C. Padmanabhan, an advocate in the High Court, Madras. Ramanujam had his primary and secondary education at Ewart’s School, Madras and later joined the Sir M. Ct. Muthia Chetty High School at Vepery, Madras. He passed his High School examination at the early age of 14 in 1952 and joined, as many talented young students in Madras did, the Loyola College, Madras, for his Intermediate and then the Mathematics Honours. He passed out of the Loyola College with the B.A. (Hons.) degree in 1957 with a second class which was unusual for a gifted student like him. During his High School and College days he was interested in Chemistry and Tennis. He had set up, in his house, a small laboratory in Chemistry and would perform experiments along with his friend Raghavan Narasimhan, now at Chicago University. The Laboratory was closed down after the ‘inevitable’, namely, a small accident.

During his Honours years he came under the guidance of the late Reverend Fr. C. Racine of the Loyola College with whom he kept up regular correspondence almost until his (Ramanujam’s) death. He had, as many students of Fr. Racine’s had, a great regard and respect, bordering on affection for Fr. Racine. On Fr. Racine’s suggestion he applied in 1957 for admission to the School of Mathematics of the Tata Institute of Fundamental Research at Bombay. In his letter to the Institute recommending Ramanujam, Fr. Racine wrote, “He has certainly originality of mind and the type of curiosity which is likely to suggest that he will develop into a good research worker if given sufficient opportunity”. Ramanujam amply justified Fr. Racine’s estimate of him. Ramanujam,
before he entered the Tata Institute, also came, briefly, under the influence of the late Professor T. Vijayaraghavan, the eminent mathematician who was, until 1954, the Director of the Ramanujan Institute of Mathematics at Madras. Ramanujam (and his friend Raghavan Narasimhan who also joined the Tata Institute in 1957) displayed a deep knowledge of Analytic Number Theory even at the time of joining the Tata Institute.

At the Tata Institute he learnt mathematics with an avidity and speed that was often frightening. He had given expert Colloquium talks and participated in seminars and displayed within two years of stay, versatility and depth in mathematics which are rare. Unfortunately however, he soon found himself in possession of a vast amount of mathematical expertise which he could not ‘cash in’, by solving problems of importance. The success of a few others at the Institute led to great frustration and Ramanujam decided to leave the Institute. He felt, wrongly of course, that he was inadequate in solving problems in mathematics and that he would be, perhaps, a better teacher in a university or a college. He began applying to various colleges and universities in India and it was lucky for the Tata Institute and Ramanujam that he was not selected in any of the places he had applied to.

It was then that he came to work with me and he started with a problem relating to Lie groups and Differential geometry connected with the work of C.L. Siegel. Early in 1961 he took up the problem regarding Diophantine equations especially related to those over algebraic number fields. The important problem was that raised by C.L. Siegel regarding the generalisation of Waring’s problem to algebraic number fields, namely, to find a $g = g(m)$ independent of the degree of the algebraic number field $K$, so that every totally positive integer $v$ with sufficiently large norm, which is in the ring $J_m(K)$ generated by $m$th powers of integers of $K$ can be written

$$v = x_1^m + \cdots + x_g^m$$

as the sum of $m$th powers of totally positive integers $x_i$. At that time many significant results were being obtained by Davenport and his co-workers D.J. Lewis and B.J. Birch. Davenport had proved that every cubic form with rational coefficients in at least $g = 32$ variables had
a non-trivial rational zero. Ramanujam set about the task of trying to
generalise Davenport’s method to cubic forms over algebraic number
fields by using Siegel’s generalisation of the major and minor arcs of
the Hardy-Littlewood-Ramanujan circle method. In this attempt he suc-
cceeded eminently by first simplifying Siegel’s method and then proving
that every cubic form in 54 variables over any algebraic number field
$K$ had a non-trivial zero over that field. Ramanujam himself knew that
the number 54 could be considerably reduced, even to Davenport’s 29;
but he was not interested in doing this. Recently Ramanujam’s idea of
proof was adapted by Pleasants who showed that Ramanujam’s result
holds with $g = 16$.

However, Waring’s problem in algebraic number fields was always
at the back of his mind. In the meantime some very interesting results
had been published. Rose Marie Stemmler had written a thesis on the
easier Waring’s problem in algebraic number fields, namely, of express-
ing $v > 0$ in the form $x_1^m \pm x_2^m \pm \cdots \pm x_g^m$. She showed that $g$ can be
bounded by an integer depending only on $m$ and not on the degree of
the field $K$ provided $m$ is, for instance, a prime number. Birch then used
a generalisation of Hua’s mean value theorem to show that indeed the
method of Stemmler gives Siegel’s conjecture in the case $m$ is a prime
$p$, and that every totally positive integer of sufficiently large norm, in
$J_p(K)$ is indeed a sum of at most $2^p + 1$ totally positive $p$th powers. The
extension of this result for arbitrary natural number $m$ was tied up with
obtaining a local to global theorem as was shown by Birch and Körner.
Ramanujam attacked the general problem of representation of elements
of $J_m(A)$, the ring generated by $m$th powers of elements of a complete
discrete valuation ring $A$, as sums of a fixed numbers of $m$th powers.
He showed that whatever $A$ might be, $8m^5$ summands would be enough.
Birch had shown, almost simultaneously, that if $s > 2^m + 1$, then every
integer of sufficiently large norm which is sum of $s, m$th powers mod-
ulo all powers of prime ideals, is itself such a sum of $m$th powers of
integers in $K$. The problem raised by Siegel was thus solved. Indepen-
dently, at about the same time, Birch also solved this $p$-adic problem by
an entirely different method.

Ramanujam was promoted as Associate Professor for his brilliant
work on Number Theory. He protested very strongly against this but was prevailed upon by friends and colleagues to accept the position. This promotion, besides being deserved in his case, also showed, as was the intention of the School of Mathematics, that promotion to any position in the Institute was possible on just brilliant accomplishments. He wrote his thesis in 1966 and early in 1967 he took his Doctoral examination at which Carl L. Siegel was one of the examiners. Siegel very greatly appreciated not only Ramanujam’s knowledge in Number Theory but also his general mathematical culture especially in Analysis.

Ramanujam had attended during the first few years of his stay at the Institute a large number of courses of lectures by visiting Professors. He wrote the notes of Lectures of Max Deuring during 1958–59 on “the theory of algebraic functions of one variable” and in 1964–65 of the lectures of I.R. Shafarevich on “minimal models and birational transformations of two dimensional schemes”. Professor Shafarevich was very appreciative of Ramanujam’s contributions to the Lecture notes. He wrote, “I want to thank him (Ramanujam) for the splendid job he has done. He not only corrected several mistakes but also complemented proofs of many results that were only stated in oral exposition. To mention some of them, he has written the proofs of the Castelnuovo theorem ... of the chain condition ..., the example of Nagata of a non-projective surface ... and the proof of Zariski’s theorem ...”. In the case of Mumford’s lectures on Abelian Varieties which he gave in 1968 at the Tata Institute, Mumford wrote, “...these lectures were subsequently written up, and improved in many ways, by C.P. Ramanujam. The present text is the result of a joint effort”, and further, “... C.P. Ramanujam continuing my lectures at the Tata Institute lectured on and wrote up notes on Tate’s theorem on homomorphisms between abelian varieties over finite fields”.

The contacts with Shafarevich and Mumford led him on to Algebraic Geometry and his progress and deep understanding in this field was phenomenal. Of his work in Algebraic Geometry, Mumford has written an excellent account which also is included in this volume. His influence on the members of the School of Mathematics was indeed very great. He was a source of inspiration and of ideas to the members of the School
C.P. Ramanujam

of Mathematics. He used to hold seminars on Commutative Algebra and on aspects of Algebraic Geometry. To talk to him on mathematics, especially Algebraic Geometry, was to get one’s ideas clarified and sometimes get one’s problems solved. He was very generous in giving his ideas, especially to the younger members of the School.

In 1964 he participated in the International Colloquium on Differential Analysis at the Institute and in 1968, the International Colloquium on Algebraic Geometry at which Grothendieck and Mumford, among others, greatly admired Ramanujam’s knowledge and virtuosity. Both of them became fast friends and admirers of his and invited him to Paris and Harvard.

It was in 1964 that he had the first of the many attacks of the cruel malady that was ultimately to take his life. The ailment was diagnosed by the medical officer to be “Schizophrenia with severe depression”. This depression made him feel that he was “inadequate” for mathematical research and he therefore decided to take a position in a University. In July 1965 he was offered a Professorship, with tenure, at the Panjab University in Chandigarh. However, he went there only for a year. He was immensely liked by colleagues and students there, but the illness struck him again and amidst tragic circumstances he had to cut short his stay there after about 8 months. Shortly after he rejoined the Tata Institute in June 1965, he received an invitation from the Institut des Hautes Etudes Scientifiques, Paris, to spend six months there. The Tata Institute deputed him to Bures-Sur-Yvette with full salary but again he returned before the projected period of stay was over, since the cruel illness struck him. I still remember his telephoning to me after arrival at Bombay airport—sans his baggage—saying that he would write to me about his ‘whereabouts in a few days’. Such bouts with his unfortunate illness continued throughout his short life. In February 1970, he wrote to the Director of the Institute, “due to personal reasons, I have to leave the Institute immediately. Please accept this letter of resignation”. The Director, rightly, refused to accept the resignation and wrote that “in his disturbed state of mind the above cannot be treated straightaway as meaningful”. However, he later resigned from the Institute and went for some time to Warwick University, at the instance of Mumford during
the Algebraic Geometry year there. He also visited Italy for some time and made many friends there. When he came back, he was requested to accept a Professorship at the Tata Institute of Fundamental Research but stay at Bangalore where the Institute had just started the programme in applications of mathematics. He lectured there on Analysis regularly and won great respect from the students as well as from many members of the Indian Institute of Science.

During the years he stayed at the Institute he had the attacks of his cruel illness several times. At those times, he resolved to take his life and it appears that once he did make a serious effort to end his life but the attempt was discovered and he was treated promptly. Due to great frustration he again decided to leave Bangalore and sever his connexion with the Tata Institute and had written several letters to me about it. He was recommended to the Indian Institute for Advanced Studies at Simla for a permanent Professorship. He died on October 27, 1974, after taking an overdose of barbiturates, before the offer was made by that Institute.

During his Bangalore days he became increasingly interested in mysticism and especially in ‘miracles’ which were being talked about in Bangalore at that time. He had many discussions with me about these ‘miracles’ and he said that he would investigate the truth about these miracles. He wanted to do this, both because of his intense curiosity and also because he was interested in finding out whether his malady could be cured through these methods. He was becoming somewhat ‘religious-minded’ and began also chanting sacred hymns.

Ramanujam was intensely human in his relations with others and honest to a fault both in mathematics and in his dealings with fellow mathematicians and students—qualities that are rare, more so now-a-days. He was modest and self-effacing. In mathematics he had very high standards, though he would not make caustic remarks about the work of others especially if it concerned a young man who was trying to come up. He would always, as he told me many a time, think about himself and his own work, which curiously enough, he felt, was incommensurate with his position at the Institute. However, when it came to promotions he applied very strict standards. He was an understanding
colleague, warm-hearted, and an evening with him could be rewarding mathematically and socially. He liked high class classical Indian music and loved books. Buying books, mostly on mathematics but sometimes on art, mysticism etc., especially first editions or rare books became an obsession with him. His enormous private library of mathematical books was bought by the Tata Institute of Fundamental Research.

Ramanujam was a very good lecturer and loved his students. His colleagues and friends loved him and got great benefit in mathematics from discussion with him. He was elected Fellow of the Indian Academy of Sciences in 1973. In his death the country in general, and the Tata Institute in particular, has lost an outstanding mathematician, a warm colleague and a great human being. He is mourned by one and all.
The work of C.P. Ramanujam in Algebraic Geometry

By D. Mumford

It was a stimulating experience to know and collaborate with C.P. Ramanujam. He loved mathematics and he was always ready to take up a new thread or to pursue an old one with infectious enthusiasm. He was equally ready to discuss a problem with a first year student or a colleague, to work through an elementary point or to puzzle over a deep problem. On the other hand, he had very high standards. He felt the spirit of mathematics demanded of him not merely routine developments but the right theorem on any given topic. He wanted mathematics to be beautiful and to be clear and simple. He was sometimes tormented by the difficulty of these high standards, but, in retrospect, it is clear to us how often he succeeded in adding to our knowledge, results both new, beautiful and with a genuinely original stamp.

Our lives and researches intertwined considerably. I first met him in Bombay in 1967–68, when he took notes on my course in Abelian Varieties and we worked jointly on refining and understanding better many points related to this theory. Later, in 1970–71, we were together in Warwick where he ran seminars on étale cohomology and on classification of surfaces. His excitement and enthusiasm was one of the main factors that made that “Algebraic Geometry year” a success. We discussed many topics involving topology and algebraic geometry at that time, and especially Kodaira’s Vanishing Theorem. My wife and I spent many evenings together with him, talking about life, religion and customs both in India and the West and we looked forward to a warm and continuing friendship. His premature death was a great shock to all who knew him. I will always miss his companionship and collaboration in
I will give a short survey of his contributions to algebraic geometry. Perhaps his most perfect piece of work is his proof that a smooth affine complex surface $X$, which is contractable and simply connected at $\infty$, is isomorphic to the plane $C^2$. The proof of this is not simple and uses many techniques; in particular, it shows how well he knew his way about in the classical geometry of surfaces! What is equally astonishing is his very striking counter-example showing that the hypothesis “simply connected at $\infty$” cannot be dropped. The position of this striking example in a general theory of 4-manifolds and particularly in a general theory of the topology of algebraic surfaces is yet to be understood. As mentioned above, the Kodaira Vanishing Theorem was an enduring interest of his. Both of us were particularly fascinated by this “deus ex machina”, an intrusion of analytic tools (i.e. harmonic forms) to prove a purely algebraic theorem. His two notes on this subject went a long way to clarifying this theorem:

(a) he proves it by merely topological, not analytic, techniques and

(b) he finds a really satisfactory definitive extension of the theorem to a large class of non-ample divisors on surfaces.

This second point is absolutely essential for many applications and was used immediately and effectively by Bombieri in his work on the pluricanonical system $|nK|$ for surfaces of general type. His result is that if $D$ is a divisor on $X$, such that $(D^2) > 0$ and $(D.C) \geq 0$ for all effective curves $C$, then $H^1(X, \mathcal{O}(\mathcal{O}(-D))) = 0$.

His earliest paper, on automorphisms group of varieties, is a definitive analysis of the way this group inherits an algebraic structure from the variety itself. This work employs the techniques of functors, e.g., families of automorphisms developed by Gröthendieck at about the same time. His paper “On a certain purity theorem” addresses itself to a question of Lang that puzzled almost all algebraic geometers at that time: given a proper surjective morphism $f : X \to Y$ between smooth varieties, is the set

$$\{ y \in Y \mid f^{-1}(Y) \text{ singular} \}$$
of codimension 1 in Y? Here he provides a topologico-algebraic analysis of one good case where it is true, and describes a counter example to the general case worked out jointly with me. We again see his fascination with the interactions between purely topological techniques and algebro-geometric ones.

This interest comes out again in his joint paper with Le Dung-Trang, whose Main Result is described in the title: “The invariance of Milnor’s number implies the invariance of the topological type”. Here they are concerned with a family of hypersurfaces in $C^{n+1}$: $F_t(z_0, \ldots, z_n) = 0$, with isolated singularities at the origin, whose coefficients are $C^\infty$ functions of $t \in [0, 1]$. They show that when Milnor’s number $\mu_t$, giving the number of vanishing cycles at the origin, is independent of $t$, then if $n \neq 2$, the germs of the maps $F_t : C^{n+1} \to C$ near 0 are independent of $t$, up to homeomorphism (if $n = 2$, they get a slightly weaker result). A beautiful and intriguing corollary is that the Artin local ring

$$C[[z_0, \ldots, z_n]]/(F, \frac{\partial F}{\partial z_0}, \ldots, \frac{\partial F}{\partial z_n})$$

already determines the topology of the map $F$ near 0.

Finally, his paper “On a geometric interpretation of multiplicity” proves essentially the following elegant theorem: If $Y \subset X$ is a closed subscheme defined by $I_Y \subset \mathcal{O}_X$, which blows up to a divisor $E \subset X'$, then

$$\left(\frac{-1}{n!}\right)^{n-1}(E^n) = \left[\text{leading coefficient of the polynomial}\right]$$

In addition to these published papers, Ramanujam made many contributions to my book “Abelian Varieties”, while writing up notes from my lectures. Reprinted here is the Appendix by him on Tate’s Theorem on abelian varieties over finite fields; and the following extraordinary theorem: It had been proven by Weil that if $X$ is a projective variety and $m : X \times X \to X$ is a morphism, then if $m$ makes $X$ into a group, $m$ must satisfy the commutative law too. Ramanujam proved that if $m$ merely possessed a 2-sided identity $(m(x, e) = m(e, x) = x)$, then $m$ must
also have an inverse and satisfy the associative law, hence make $X$ into a group!
For sheer elegance and economy, I have come across few mathematicians who were C.P. Ramanujam’s equal. He made so many remarks which clarified and threw light on different branches of mathematics that personally I derived immense mathematical pleasure in his company. I list below three of his unpublished mathematical comments which exemplify his mathematical style.

1. *Any two points of an irreducible variety can be connected by an irreducible curve.* To prove this one notices that by Chow’s lemma, one may assume that the variety in question is projective. Then one could blow up the two points and in any projective imbedding of this blow-up, take a generic hyperplane section which is irreducible of lower dimension. Since this hyperplane meets the two exceptional divisors, the problem reduces to one of lower dimension and hence proves the assertion by induction.

2. In the early days of algebraic $K$-theory, M.P. Murthy asked me if I could think of any example to show that $SL(2, A) \to SL(2, A/p)$ need not be surjective. I suggested that as a universal example (for $C$-algebras), one should take $A = C[X, Y, Z, T]$, $p =$ the principal ideal generated by $XY – ZT$ and try to show that $(\bar{X} \bar{Z} \bar{T} \bar{Y})$ in $SL(2, A/p)$ cannot be in the image of an element in $SL(2, A)$. Ramanujam, who was around, immediately came up with the following proof unbeatable for its beauty and simplicity.

Let $\begin{pmatrix} f & k \\ h & g \end{pmatrix}$ be the unimodular matrix over $A$ reducing to $\begin{pmatrix} \bar{X} & \bar{T} \\ \bar{Z} & \bar{Y} \end{pmatrix}$. 
Then the map $M(2, C) \to SL(2, C)$ given by
\[
\begin{pmatrix} x & t \\ z & y \end{pmatrix} \mapsto \begin{pmatrix} f(x, y, z, t) & k(x, y, z, t) \\ h(x, y, z, t) & g(x, y, z, t) \end{pmatrix}
\]
is easily seen to be a retraction, which is impossible since $M(2, C)$ is contractible, and $SL(2, C)$ is homotopically equivalent to the three dimensional sphere.

3. In our study of the moduli of stable vector bundles with trivial determinant over a projective nonsingular curve of genus 2, M.S. Narasimhan and I came upon the following question: If $X$ is a 3-dimensional projective nonsingular curve, and $Y \subset X$ an ample divisor isomorphic to $P^2$ with $X - Y$ simply connected, can one conclude that $X$ is isomorphic to $P^3$? Ramanujam’s solution of this problem follows.

**Theorem.** Let $X$ be a projective, nonsingular variety of dimension $n \geq 3$ and $Y \cong P^{n-1}$ a closed subvariety of $X$ of codimension 1, with $X - Y$ affine and $H_1(X - Y, Z)$ torsion free. Then $X \cong P^n$.

**Proof.** By Lefschetz, valid even under the assumption $X - Y$ affine, $H_i(Y) \to H_i(X)$ is an isomorphism for $i \leq n - 2$ and surjective for $i = n - 1$. Now if $n$ is even, $H_{n-1}(Y) = 0$, while if $n$ is odd, $H_{n-1}(Y) \cong Z$ and rank $H_{n-1}(X)$ is clearly $\geq 1$, so that in any case, $H_i(Y) \to H_i(X)$ is an isomorphism for $i \leq n - 1$. By the universal coefficient theorem, so is $H^i(X) \to H^i(Y), i \leq n - 1$. In particular, $H^1(X) = 0, H^2(X) = Z$ and $H^1(X, \mathcal{O}_X) = H^2(X, \mathcal{O}_X) = 0$. Thus we obtain $H^1(X, \mathcal{O}_X^*) \cong H^2(X, Z) \approx Z$ and that $H^1(X, \mathcal{O}_X^*) \to H^1(Y, \mathcal{O}_Y^*)$ is an isomorphism.

We wish to show that the line bundle $L = L_Y$ defined by the divisor $Y$ generates $H^1(X, \mathcal{O}_X^*)$, or what is the same, the Poincaré dual of the class in $H_{2n-2}(X)$ defined by $Y$ generates $H^2(X, Z)$. Since $H_{2n-2}(Y) \to H_{2n-2}(X)$ is clearly nontrivial and $H_{2n-2}(X) \cong H^2(X) \cong Z$, it is enough to show that $H_{2n-2}(X, Y)$ has no torsion. But this follows from the assumption that $H_1(X - Y) \cong H^{2n-1}(X, Y)$ has no torsion.
Now $L/Y$ generates $H^1(Y, \mathcal{O}_Y^*)$. Let $f$ be a nonconstant rational function, regular on $X - Y$ and having a pole of order $r$ along $Y$. If $\sigma$ is the canonical section of $L$, then $f \sigma^r|Y$ is a nonzero section of $L'|Y$ and hence $L|Y$ cannot be negative. Thus $L|Y$ is ample.

For any $p \in \mathbb{Z}$, consider the exact sequence

$$0 \to L^{p-1} \xrightarrow{\otimes \sigma} L^p|Y \to 0.$$  

One deduces, by induction from the cohomology exact sequence, that

(i) for $p \geq 0$, $H^1(X, L^p) = 0$ and hence

(ii) for $p \geq 1$,

$$0 \to H^0(X, L^{p-1}) \to H^0(X, L^p) \to H^0(Y, L^p) \to 0$$

is exact. Thus in the graded algebra $A = \sum_{p \geq 0} H^0(X, L^p)$ there is an element $\sigma$ of degree 1 which is not a zero divisor such that $A/\sigma$ is a polynomial algebra in $(n - 1)$ variables. From this it is easy to conclude that $A$ itself is a polynomial algebra in $n$ variables. Thus for some $d > 0, L^d$ is very ample and the homogeneous coordinate ring of $X$ for the projective imbedding given by $L^d$ is the same as that for $P^n$ for the $d$-fold Segre imbedding. Hence $X \cong P^n$, is itself very ample and $Y$ is a hyperplane.

\[ \Box \]
JANUARY 9, 1938 --- OCTOBER 27, 1974
The dominated convergence theorem.

If \( f_n \in L^1(x, \nu) \), \( f_n \to f \text{ a.e.} \) and \( f \in L^1(x, \nu) \), then \( f_n \to f \text{ in } L^1(x, \nu) \).

**Proof.** In fact, by the dominated convergence theorem for real-valued functions, \( \| f_n - f \|_1 \to 0 \) as \( n \to \infty \), so \( f \in L^1(x, \nu) \) such that \( f \to f \) in \( L^1(x, \nu) \). Replacing by a subsequence if necessary, \( f \) is a.e. finite. Hence \( f \) is a.e. finite. \( \square \)

**Definition.** A function \( f : X \to \nu \) is measurable if it is the almost everywhere limit of a sequence of \( \nu \)-measurable functions (i.e., \( \nu \)-measurable linear combinations of characteristic functions of measurable sets, not necessarily finite to measure).

**Theorem.** In a function \( f : X \to \nu \), the following one is equivalent:

1. \( f \) is measurable
2. \( f^{-1}(U) \) is measurable for every \( U \) open in \( \nu \) and \( \exists E \subset X, \mu(E) = 0 \) such that \( f \) is measurable on \( X - E \).
3. For every \( E \in \nu^* \), \( \mu(E) = 0 \) is measurable and \( \exists E \subset X, \mu(E) = 0 \) such that \( f \) is measurable on \( X - E \).

Facsimile of a page from Ramanujam's Notes on Analysis
Cubic forms over algebraic number fields

By C.P. Ramanujam

Tata Institute of Fundamental Research, Bombay
Communicated by H. Davenport
(Received 3 September 1962)

Davenport has proved [3] that any cubic form in 32 or more variables with rational coefficients has a non-trivial rational zero. He has also announced that he has subsequently been able to reduce the number of variables to 29. Following the method of [3], we shall prove that any cubic form over any algebraic number field has a non-trivial zero in that field, provided that the number of variables is at least 54. The following is the precise form of our result.

**Theorem.** Let $K$ be any algebraic number field and let $C(X) = C(X_1, \ldots, X_m)$ be any homogeneous cubic form with coefficients in $K$. If the number $m$ of variables is greater than 53, there exist $X_0^1, \ldots, X_m^0$ in $K$, not all zero, such that $C(X_0^1, \ldots, X_m^0) = 0$.

Throughout this paper, we shall use the following notations:

- $\Gamma$, $R$ and $C$ denote the fields of rational, real and complex numbers respectively.
- $K$ is a finite algebraic extension of $\Gamma$ of degree $n$.
- $Z$ and $\mathfrak{o}$ are the rings of integers of $\Gamma$ and $K$ respectively, and $\mathfrak{d}$ the different ideal of $K$ over $\Gamma$.
- $\omega_1, \ldots, \omega_n$ is a basis of $\mathfrak{o}$ over $Z$, and $\rho_1, \ldots, \rho_n$ the dual basis of $\mathfrak{d}^{-1}$ over $Z$, determined uniquely by the conditions $S(\omega_i \rho_j) = \delta_{ij}$, where $S$ denotes the trace over $\Gamma$. 

21
$K_R$ is the $n$-dimensional commutative algebra $R \otimes \Gamma K$ over $R$; we identify an element $x$ of $K$ with the element $1 \otimes x$ of $K_R$; then $\omega_1, \ldots, \omega_n$ form a basis of $K_R$ over $R$, and for any $y$ in $K_R$, we write $y = \sum y_i \omega_i$. For any $y \in K_R$, $S(y)$ and $N(y)$ will denote the trace and norm respectively of $y$ over $R$. By a box $B = B(a_1, b_1, \ldots, a_n, b_n)$ in $K_R$, where the $a_i, b_i$ are real numbers with $0 < b_i - a_i \leq 1$, we shall mean the set of $y$ in $K_R$ with $a_i \leq y_i < b_i (i = 1, \ldots, n)$. $B_0$ will denote the set of $y$ in $K_R$ with $-1 \leq y_i < 1$.

$(K_R)^m$ will denote the $m$th Cartesian power of $K_R$, considered as an $mn$-dimensional vector space over $R$. A box $B$ in $(K_R)^m$ is the Cartesian product $\prod_{i=1}^m B_i$ of boxes $B_i$ in $K_R$; similarly, $B_0$ will denote $(B_0)^m$.

Unless otherwise stated, all summations will be over ‘integral’ vectors $X = (X_1, \ldots, X_m)$ of $(K_R)^m, X_i \in a$, which are subject to the conditions stated either under the summation sign or immediately after.

For real values of $x$, $e(x)$ will denote $e^{2\pi i x}$ as usual and $||x||$ the distance of $x$ from the nearest integer. We shall use the $O, o,$ notation of Landau-Bachmann as well as the $\ll$ notation of Vinogradoff, whichever is more convenient. The parameters on which the constants involved in these notations depend will be explicitly mentioned, if not clear from the context.

## 1 General cubic exponential sums

Since the estimations of this and the next sections are straightforward extensions of those of the corresponding §§ 3 and 4 of [3], we shall only state the results or give brief sketches of the proofs, referring to [3] for details.

Let

$$\Gamma(X) = \sum_{i,j,k=1}^m \gamma_{ijk} X_i X_j X_k$$

be a cubic form with coefficients in $K_R$ which are symmetric in all three indices. We associate to this cubic form the bilinear forms $B_j(X, Y) (j = 1, \ldots, m)$ on $(K_R)^m$ with values in $K_R$ and the bilinear forms $\lambda_{jp}(X, Y)$
(j = 1, . . . , m; p = 1, . . . , n) on (KR)m with values in R by means of the equations

\[ B_j(X, Y) = \sum_{i, k} \gamma_{ijk} X_i Y_k = \sum_{p=1}^{n} \lambda_{jp}(X, Y)_{p_p}. \]

For a box \( \mathcal{B} \) in (KR)m and a real \( P > 1 \), we set

\[ S = S(P, \mathcal{B}) = \sum_{X \in P \mathcal{B}} e(S(\Gamma(X))). \]

Throughout this section, the constant implied by the sign \( \ll \) will depend only on \( m \) and \( n \), and will in particular be independent of the coefficients of \( \Gamma(X) \).

**Lemma 1.1.**

\[ |S|^4 \ll P^{mn} \sum_{X, Y \in P \mathcal{B}_0} \prod_{j=1}^{m} \prod_{p=1}^{n} \min \left( P, ||\lambda_{jp}(X, Y)||^{-1} \right). \]

This is proved by following the first step of Weyl’s method of estimating trigonometrical sums in one variable, exactly like Lemma 3.1 of [3].

The above lemma remains valid even if \( \Gamma(X) \) contains quadratic and linear terms, as the proof of the lemma shows. This remark will be useful to us later.

We now find conditions under which the inequality

\[ |S| > P^{(m-\kappa)n} \] \hspace{1cm} (1)

will be valid, where \( 0 < \kappa < m \).

**Lemma 1.2.** Suppose (1) holds and let \( N \) denote the number of distinct pairs of integral points \( X, Y \) satisfying

\[ X, Y \in P \mathcal{B}_0, \quad ||\lambda_{jp}(X, Y)|| < P^{-1}; \]

then

\[ N \gg P^{(2m-4\kappa)n} (\log P)^{-mn}. \]
Proof. If \( \{x\} \) denotes the fractional part of \( x \) for real \( x \), and \( r_{jp}(j = 1, \ldots, m; p = 1, \ldots, n) \) are integers satisfying \( 0 \leq r_{jp} \leq P \), the simultaneous inequalities

\[
P^{-1}r_{jp} \leq \{6\lambda_{jp}(X, Y)\} < P^{-1}(r_{jp} + 1)
\]

cannot hold for more than \( N(X) \) integer points, \( Y \) lying in any fixed box with edges not exceeding \( P \) in length, where \( N(X) \) denotes for any \( X \in P0 \) the number of \( Y \) satisfying the inequalities stated in the lemma. Since \( P0 \) can be subdivided into \( 2^{mn} \) such boxes, we obtain

\[
\sum_{Y \in P0} \prod_{j=1}^{m} \prod_{p=1}^{n} \min\left( P, \|6\lambda_{jp}(X, Y)\|^{-1} \right)
\leq N(X) \prod_{j,p} \sum_{r_{jp}=0}^{P-1} \min\left( P, \frac{P}{r_{jp}}, \frac{P}{P - r_{jp} - 1} \right)
\leq N(X)(P \log P)^{mn};
\]

summing over all \( X \in P0 \) and applying Lemma 1.1, we get the estimate for \( N \).

\[\square\]

**Lemma 1.3.** Suppose (1) holds, and let \( 0 < \theta < 1 \). Let \( N_2 \) denote the distinct pairs of integer points \( X, Y \) satisfying

\[
X, Y \in P^\theta 0, \quad \|6\lambda_{jp}(X, Y)\| < P^{-3+2\theta}.
\]

Then

\[
N_2 \geq \left( P^{2m\theta-4\kappa} (\log P)^{-m} \right)^n.
\]

**Proof.** For fixed \( X \) and \( Y_i = \sum_{q=1}^{n} Y_{iq}\omega_q \), we have

\[
6\lambda_{jp}(X, Y) = 6S \left( B_j(X, Y)\omega_p \right) = 6 \sum_{k,q} S \left( \sum_{i} \gamma_{ijk} X_i \omega_p \omega_q \right) Y_{k,q},
\]

which shows that the coefficient of \( Y_{k,q} \) in \( 6\lambda_{jp} \) is equal to the coefficient of \( Y_{jp} \) in \( 6\lambda_{k,q} \). Thus we may apply Lemma 3.3 of [3] to the forms in \( Y \).
obtained by substituting a fixed value of $X$ in $6\lambda_{jp}(X,Y)$, and similarly also to the forms in $X$ obtained by fixing $Y$.

Fixing $X$ in $P\mathcal{B}_0$ and applying the aforementioned lemma to the forms $6\lambda_{jp}(X,Y)$ in $Y$ with $A = P,Z_1 = P^{-1+\theta}, Z_2 = 1$, and summing over all integral $X$ in $P\mathcal{B}_0$, we find that the number $N_1$ of distinct pairs of integral points $X,Y$ satisfying

$$X \in P\mathcal{B}_0, \quad Y \in P^0\mathcal{B}_0, \quad ||6\lambda_{jp}(X,Y)|| < P^{-2+\theta}$$

is $\gtrsim P^{(n+m\theta-4\kappa)n}(\log P)^{mn}$, by Lemma 1.2. Another application of the lemma to the forms in $X$ obtained by fixing $Y \in P^0\mathcal{B}_0$ with $A = P^\frac{1}{2}(3-\theta)$,

$Z_1 = P^{-\frac{3}{2}(1-\theta)}, Z_2 = P^{-\frac{1}{2}(1-\theta)}$, and summation over $Y$, gives the result. \hfill \square

**Definition.** Let $m,n,r,\kappa,\theta(0 < \theta < 1), \delta(> 0)$, be given with $m\theta > 4\kappa$. For $P > 1$, define $r$ to be the greatest positive integer with the
property that there exists a non-zero integer point $X$ and $r$ integer points $Y^{(1)}, \ldots, Y^{(r)}$ independent over $K$ such that

$$X \in P^\theta B_0, \quad Y^{(s)} \in P^\theta B_0, \quad \|6\lambda_{jp}(X, Y^{(s)})\| < P^{-3+2\theta+\delta}$$

for $s = 1, \ldots, r$.

Note that under assumption (P) and for $P$ large, $r \geq 1$ by Lemma 1.3.

**Lemma 1.5.** Suppose that

$$0 < \xi \leq \theta, \quad 0 < \eta \leq \theta, \quad 0 < B \leq P^{-3+2\theta+\delta}$$

and that $\lambda$ and $\epsilon$ are positive satisfying

$$\lambda > m\xi, \quad \lambda > r\eta.$$

Then there exists a $P_0 = P_0(m, n, \xi, \eta, \theta, \delta, \lambda, \epsilon)$, such that if $P > P_0$ and there are more than $P^{(\lambda+\epsilon)n}$ distinct pairs of integer points $X, Y$, neither zero, satisfying

$$X \in P^\xi B_0, \quad Y \in P^n B_0, \quad \|6\lambda_{jp}(X, Y)\| < B,$$  \hspace{1cm} (2)

then

$$\lambda + \epsilon \leq m\xi + r\eta,$$

and there are more than $P^{mn\xi}$ distinct pairs of integer points $X, Y$ neither zero, with

$$X \in P^\xi B_0, \quad Y \in P^{\eta-(\lambda-m\xi)/r} B_0, \quad \|6\lambda_{jp}(X, Y)\| < 2B.$$

**Proof.** For each $X \neq 0$, let $T(X)$ denote the number of $Y \neq 0$ satisfying (2). Because of the assumptions on $\xi, \eta$ and $B$, we can apply the first part of Lemma 1.4 to deduce that

$$T(X) \leq AP^{mn\eta};$$

since by assumption

$$\sum_{X \in P^\xi B_0 \atop X \neq 0} T(X) \geq P^{(\lambda+\epsilon)n}$$
We deduce that $P^{n(\lambda + \epsilon) - mn\xi - r\eta} \leq A$, which shows that $\lambda + \epsilon \leq m\xi + r\eta$ unless $P$ is small (the smallness as made precise in the statement of the lemma).

For $s = 0, 1, 2, \ldots$, let $X_s$ denotes the number of integer points $X \neq 0, X \in P^n B_0$, for which

$$AP^{\eta n} 2^{-s-1} \leq T(X) < AP^{\eta n} 2^{-s}.$$ 

It is clearly sufficient to take $\leq \log P$ values of $s$ to include all $X$ for which $T(X) \neq 0$. Since we have

$$AP^{\eta n} \sum_{s=0}^{\infty} 2^{-s} X_s > P^{(\lambda + \epsilon)n},$$

there exists at least one $s$ for which

$$P^{\eta n} 2^{-s} X_s \geq A' P^{(\lambda + \epsilon)n} (\log P)^{-1},$$

$A'$ being a constant dependent only on $m$ and $n$. For this $s$, and $\rho$ defined by the equation $P^\rho = P^{\eta n} - \frac{1}{2} en 2^{-s}$, we have

$$X_s \geq A''(m, n, \epsilon) P^{\ln - \rho + \frac{1}{2} en},$$

and since $X_s \leq P^{mn}$ trivially, it follows that $\rho > \lambda n - mn\xi + \frac{1}{4} en$ unless $P$ is small.

Assuming $P$ large enough, we now have $X_s$, integer points $X \neq 0$ to each of which there correspond $T(X)$ integer points $Y \neq 0$ such that (2) is satisfied. We apply to the set of points $Y$ corresponding to a particular $X$ the second part of Lemma 1.4 with

$$y = P^\eta, \quad T = T(X) \geq \frac{1}{2} A P^{\rho + \frac{1}{2} en}, \quad W = \left[ P^{\rho - \lambda n + mn\xi} \right] + 1.$$ 

The condition $1 < W < T(X)$ is satisfied since $0 < n(\lambda - m\xi) < \rho$. We thus deduce that to each of the $X_s$ points there correspond $W$ distinct points $Y^{(1)}, \ldots, Y^{(W)}$ with

$$Y^{(1)} - Y^{(W)} \in B^1 P^\eta P^{(\rho - \lambda n + mn\xi)/r} n P^{-(\rho + \frac{1}{2} en) r} B_0 = B^1 P^{\eta - (\lambda - m\xi)/r - \frac{1}{2} en} B_0.$$
where $B^1$ is a constant depending only on $m$ and $n$. Denoting $Y^{(1)} - Y^{(w)}$ by $Y''^{(w)}$, we see that to each of the $X_s$ points there correspond $W - 1$ distinct integer points $Y \neq 0$ satisfying

$$Y \in P^{\eta - \{(\lambda - m\xi)/r\}} B_0, \quad ||6\lambda_{jp}(X,Y)|| < 2B,$$

if $P$ is large enough. All the resulting pairs satisfy the condition of our lemma, and their number is

$$(W - 1)X_s \geq \frac{1}{2}A'' P^{\rho - \lambda n + mn\xi} P^{\lambda n - \rho + \frac{\epsilon}{2n}} p^{mn\xi}$$

if $P$ is large.

\[\square\]

The lemma is thus proved.

**Lemma 1.6.** Let $m, \kappa, \theta (0 < \theta < 1)$ and $\delta (> 0)$ be fixed independently of $P$ and suppose that $m\theta > 4\kappa$ and that (I) holds. Then there exists a $P_1$ depending only on $m, n, \theta, \kappa$ and $\delta$ such that for $P \geq P_1$, we have

$$r \geq m - 2\kappa/\theta.$$ 

**Proof.** The proof simply consists of repeated applications of the previous lemma, though the details are complicated.

We define several sequences of numbers depending on $m, n, \kappa, \theta$ and $\delta$ and on certain positive parameters $\epsilon_0, \epsilon_1, \ldots$, which will later be fixed in terms $m, n, \kappa, \theta$ and $\delta$, as follows:

$$\begin{align*}
\xi_0 &= \theta, \quad \eta_0 = \theta, \quad B_0 = P^{-3+2\theta}, \quad \lambda_0 = 2m\theta - 4\kappa - 2\epsilon_0, \\
\xi_{q+1} &= \eta_q - \frac{(\lambda_q - m\xi_q)}{r}, \quad \eta_{q+1} = \xi_q, \quad B_{q+1} = 2B_q, \quad \lambda_{q+1} = \\
&= m\xi_q - \epsilon_{q+1}, \\
\end{align*}$$

for $q \geq 0$.

On substituting for $\eta_q$ and $\lambda_q$ in the expression for $\xi_{q+1}$ when $q \geq 1$, we obtain

$$\xi_{q+1} = \xi_{q-1} - \frac{(m\xi_{q-1} - \epsilon_q - m\xi_q)}{r},$$

where $B^1$ is a constant depending only on $m$ and $n$. Denoting $Y^{(1)} - Y^{(w)}$ by $Y''^{(w)}$, we see that to each of the $X_s$ points there correspond $W - 1$ distinct integer points $Y \neq 0$ satisfying
\[ \xi_q - \xi_{q+1} = \omega (\xi_{q-1} - \xi_q) - \frac{1}{r} \epsilon_q, \]

where \( \omega = m/r - 1 \), and hence by induction,

\[ \xi_q - \xi_{q+1} = \omega^q (\xi_0 - \xi_1) - \frac{1}{r} \sum_{t=1}^{q} \epsilon_t \omega^{q-t} \quad (q \geq 1). \]

Summation gives

\[ \xi_0 - \xi_{q+1} = (\xi_0 - \xi_1) \sum_{s=0}^{q} \omega^s - \frac{1}{r} \sum_{s=0}^{q} \sum_{t=1}^{q} \epsilon_t \omega^{s-t}. \]

Now assume contrary to the required conclusion that \( r < m - 2\kappa/\theta \).

Since \( r \) is an integer, it follows that \( m - 2\kappa/\theta - r \) must be greater than a positive number depending only on \( m, \kappa \) and \( \theta \). We shall show that there exist \( \phi(m, n, \theta, \kappa) > 0 \) and an integer \( Q = Q(m, n, \theta, \kappa) \) such that for \( \epsilon_0 < \phi(m, n, \theta, \kappa) \) we have

\[ \xi_0 - \xi_1 > \frac{m\theta - 4\kappa}{2m} \]

and

\[ \xi_0 < (\xi_0 - \xi_1) \sum_{s=0}^{Q} \omega^s. \]

The first is clearly ensured if \( \epsilon_0 < (m\theta - 4\kappa)/2m \). It follows that if \( \omega \geq 1 \), we can ensure the second by taking \( Q + 1 > 2m\theta/(m\theta - 4\kappa) \). Hence assume \( \omega < 1 \), that is,

\[ \omega \leq 1 - 1/m. \]

Since \( \xi_0 - \xi_1 \) is bounded above by 2, it is clearly enough to show that if \( \epsilon_0 \) is small enough,

\[ \xi_0 < (\xi_0 - \xi_1) \sum_{s=0}^{\infty} \omega^s = (1 - \omega)^{-1} (\xi_0 - \xi_1), \]

i.e.

\[ \theta < \frac{r}{2r - m} \frac{(m\theta - 4\kappa - 2\epsilon_0)}{r} = \frac{m\theta - 4\kappa - 2\epsilon_0}{2r - m}, \]
i.e.  

\[ 2r < 2m - \frac{3\kappa}{\theta} - \frac{2\epsilon_0}{\theta}, \]

which holds if \( \epsilon_0 \) is less than \( \theta(m - 2\kappa/\theta - r) \), and hence if \( \epsilon_0 \) is less than \( \phi'(m, n, \kappa, \theta) \). It follows easily that for \( \epsilon_0 < \phi'(m, n, \kappa, \theta) \), we have

\[ \xi_0 < (\xi_0 - \xi_1) \sum_{s=0}^{Q} \omega^s + \mu(m, n, \kappa, \theta), \]

where \( \mu(m, n, \kappa, \theta) > 0 \). Hence it follows that there exists a

\[ \psi(m, n, \kappa, \theta) > 0 \]

such that if \( \epsilon_i < \psi(m, n, \kappa, \theta) \) for \( i = 0, \ldots, Q \) we have

\[ \xi_0 < (\xi_0 - \xi_1) \sum_{s=0}^{Q} \omega^s - \frac{1}{r} \sum_{s=0}^{Q} \sum_{t=1}^{s} \epsilon_i \omega^{s-t} = \xi_0 - \xi_{Q+1}, \]

\[ \xi_{Q+1} < 0. \]

We shall now choose \( \epsilon_i \) suitably depending only on \( m, n, \theta, \kappa \) and \( \delta \) to show that if the above inequality holds, \( P \) must be bounded above by a function of these parameters.

For every \( q \leq Q \), we wish to choose \( \epsilon_0, \ldots, \epsilon_q \) with \( \epsilon_i < \psi(m, n, \kappa, \theta) \) and \( P_q(m, n, \kappa, \theta, \delta) \) such that the following conditions hold:

\[ \xi_s > 0, \quad \xi_s - \xi_{s+1} > 0, \quad \lambda_s > m\xi_s, \quad \lambda_s > r\eta_s \quad (s = 0, \ldots, q), \]

and if \( P > P_q \), the inequalities

\[ X \in P_{\xi_0}^k \mathcal{B}_0, \quad Y \in P_{\eta_0}^n \mathcal{B}_0, \quad ||6\lambda_{jp}(X, Y)|| < B_s \]

have at least \( P(n, \lambda_s + \epsilon_i) \) pairs of solutions with \( X, Y \neq 0 \).

For \( q = 0 \), choose \( \epsilon_0 = \frac{1}{2}\psi(m, n, \kappa, \theta) \). It follows from our previous considerations that the first set of conditions hold. Also by Lemma 13, the second set of inequalities has \( \geq \left( P^{2m\theta - 4\kappa} (\log P)^{-m} \right)^n \) solutions. Since the number of solutions with \( X = 0 \) or \( Y = 0 \) is \( \leq P^{mn\theta} \) and
mn\theta < 2mn\theta - 4kn$, we deduce that if $P > P_0(m, n, \kappa, \theta)$, the number of solutions with $X \neq 0, Y \neq 0$ is \[ \geq (P^{2m\theta-4k-\epsilon_0})^n = P^n(\lambda_0 + \epsilon_0). \]

Suppose we have now chosen $\epsilon_0, \ldots, \epsilon_q$ and $P_q$ depending only on $m, n, \kappa$ and $\theta$ satisfying our conditions. Applying Lemma 1.5 to the second set of inequalities with $s = q$, we deduce that if $P \geq \max(P_q, P_0(m, n, \xi_q, \eta_q, \theta, \delta, \lambda_q, \epsilon_q)) = P_{q+1}(m, n, \theta, \delta, \kappa)$, we have

\[ \lambda_q + \epsilon_q \leq m\xi_q + rn\eta_q, \]

and that the number of pairs $X, Y$ with $X \neq 0, Y \neq 0$ satisfying

\[ X \in P^{\xi_q}B_0, \ Y \in P^{\eta_q - (\lambda_q - m\xi_q)}/r, \ ||6\lambda_j p(X, Y)|| < B_{q+1} \]

is greater than $P^{mn\xi_q} = P^n(\lambda_{q+1} + \epsilon_{q+1})$. Since $\lambda_j p(X, Y) = \lambda_j p(Y, X)$ we may interchange $X$ and $Y$ in the above set of inequalities to deduce that the second set of conditions are satisfied for $s = q + 1$. As to the first set, we have

\[ \xi_{q+1} = \eta_q - \frac{(\lambda_q - m\xi_q)}{r} > 0, \]

\[ \xi_{q+1} - \xi_{q+2} = \omega(\xi_q - \xi_{q+1}) - \frac{1}{r}\epsilon_{q+1} > 0, \]

if $\epsilon_{q+1} < \omega(\xi_q - \xi_{q+1})$, and since the right-hand side depends only on $m, n, \kappa, \theta, \delta$, if $\epsilon_{q+1} < \psi_{q+1}(m, n, \kappa, \theta, \delta)$. Also

\[ \lambda_{q+1} - m\xi_{q+1} = m(\xi_q - \xi_{q+1}) - \epsilon_{q+1} > 0 \]

again if $\epsilon_{q+1} < \psi'_{q+1}(m, n, \kappa, \theta, \delta)$; and finally,

\[ \lambda_{q+1} - rn\eta_{q+1} = (m - r)\xi_q - \epsilon_{q+1} > 0, \]

if $\epsilon_{q+1} < \psi''_{q+1}(m, n, \kappa, \theta, \delta)$. Thus if we choose

\[ \epsilon_{q+1} = \frac{1}{2} \min(\psi_{q+1}, \psi'_{q+1}, \psi''_{q+1}), \]

all our conditions are satisfied and our induction is complete.

Thus we obtain for $s = Q + 1$ that $\xi_{Q+1} > 0$ unless $P < P_{Q+1}(m, n, \kappa, \theta, \delta)$ and since we have already shown that $\xi_{Q+1} < 0$ (and since $Q$ depends only on $m, n, \kappa, \theta, \delta$) we deduce that if $r < m - 2k/\theta$, $P$ must necessarily be bounded by a function of $m, n, \kappa, \theta$ and $\delta$. The proof of the lemma is complete. \[ \square \]
2 Two particular types of exponential sums

Let

\[ C(X) = C(X_1, \ldots, X_m) = \sum_{i,j,k=1}^{m} c_{ijk} X_i X_j X_k \]

be a cubic form with coefficients which are integers of \( K \), symmetric in all three indices. We shall assume throughout this section that \( C(X) \) does not represent zero non-trivially; that is, that \( X \neq (0, \ldots, 0) \) is the only solution of \( C(X) = 0 \) in \( K \).

The cubic form \( C(X) \) is said to represent the cubic form \( C'(U) = C'(U_1, \ldots, U_s) \) in the \( s \) variables \( U_1, \ldots, U_s \) if there exists a linear transformation

\[ X_i = \sum_{t=1}^{s} p_{it} U_t, \quad p_{it} \in \mathbb{Z} \quad (i = 1, \ldots, m; t = 1, \ldots, s), \]

of rank \( s \) which transforms \( C(X) \) into \( C'(U) \). It follows that we must have \( s \leq m \). We shall say that \( C(X) \) splits with remainder \( r \) if it represents a form in \( r + 1 \) variables of the type

\[ a_0 U_0^3 + C_1(U_1, \ldots, U_r). \]

We define the following bilinear forms (not to be confused with the \( B_j \) defined in §1) associated to \( C(X) \):

\[ B_j(X, Y) = \sum_{i,k} c_{ijk} X_i Y_k. \]

**Lemma 2.1.** Suppose there is a non-zero integral point \( Z \) and \( r \) linearly independent integral points \( Y^{(1)}, \ldots, Y^{(r)} \) such that

\[ B_j(Z, Y^{(s)}) = 0 \quad (j = 1, \ldots, m; s = 1, \ldots, r). \]

Then \( r \leq m - 1 \), and \( C(X) \) splits with remainder \( r \).

**Proof.** The linear transformation

\[ X_i = Z_i U_0 + Y_i^{(1)} U_1 + \cdots + Y_i^{(r)} U_r \]
can be easily seen to be of rank precisely \( r + 1 \), and transforms \( C(X) \) into a form of the type \( a_0 U_0^3 + C^1(U_1, \ldots, U_r) \), proving our assertion.

We will now apply Lemma 1.6 to two particular exponential sums which will arise in our later work.

Let \( \mathcal{B} \) be a fixed box in \((K_R)^n\); for any \( \alpha \in K_R \) and \( P > 1 \), we define

\[
E(\alpha) = \sum_{X \in P \mathcal{B}} e(S(\alpha C(X))).
\]

Let \( \delta \) be any positive number. We then have

\[
\text{LEMMA 2.2. Let } \kappa \text{ and } \theta \text{ be fixed numbers satisfying}
0 < \theta < 1, \quad 0 < 4\kappa < m\theta.
\]

Let \( C(X) \) be any cubic form over \( K \) with integral coefficients which does not represent zero non-trivially and which does not split with remainder \( r \), where \( r \) is the least integer satisfying

\[
r \geq m - \frac{2\kappa}{\theta}.
\]

Then there exists a \( P_0 \) (depending on \( K, C, \theta, \kappa \) and \( \delta \)) such that for \( P \geq P_0 \), either

\[
|E(\alpha)| \leq P^{(m-\kappa)n} \tag{4}
\]

or there exists an integer \( \mu \in \mathcal{O}, \mu \neq 0 \), and \( \mu \in P^{2\theta+\delta} \mathcal{B}_0 \), and a \( \lambda \in d^{-1} \) such that

\[
\mu \alpha - \lambda = \sum_{i=1}^{n} e_i P_i, \quad e_i \in R, \quad |e_i| < P^{-3+2\theta+\delta}. \tag{5}
\]

Proof. We apply Lemma 1.6 with \( \Gamma(X) = \alpha C(X) \). It follows that for large \( P \), either (4) holds or there exists an integral point \( X \) and \( r \geq m - 2\kappa/\theta \) integral points \( Y^{(1)}, \ldots, Y^{(r)} \), in \( P^\theta \mathcal{B}_0 \), linearly independent over \( K \), such that the following conditions hold:

\[
6\alpha B_j(X, Y^{(s)}) = \lambda_{j,s} + \sum_i e_i(j, s) \rho_i, \quad \lambda_{j,s} \in d^{-1}, \quad e_i(j, s) \in R,
\]
\[ |\varepsilon_i(j, s)| < P^{-3+2\theta+\delta} \quad (i, j = 1, \ldots, n; s = 1, \ldots, r). \]

All the \( B_j(X, Y^{(s)}) \) cannot be zero, since it would then follow from Lemma [2.1] that \( C(X) \) splits with remainder \( r \). Also since \( X, Y^{(s)} \in P^\theta \mathcal{B}_0 \), it follows that

\[ 6B_j(X, Y^{(s)}) \in AP^{2\theta} \mathcal{B}_0, \]

where \( A \) is a constant depending only on \( K \) and \( C \). Our lemma therefore follows if we take \( \mu = 6B_j(X, Y^{(s)}) \) with \( j \) and \( s \) so chosen that \( B_j(X, Y^{(s)}) \neq 0 \).

We note that in view of the remark made at the end of Lemma [1.1] the above lemma holds without change even if we replace the sum \( E(\alpha) \) by the sum

\[ \sum_{X \in P\mathcal{B}} e(S(\alpha C(X)) + L(X)), \]

where \( L(X) \) is a real linear form in the \( X_{ij} \).

Now let \( \gamma \) be any non-zero element of \( K \). We associate with \( \gamma \) the integral ideal \( a_\gamma \) which is the denominator of \( (\gamma) d \), that is to say \( a_\gamma = (g.c.d(\alpha, \gamma d))^{-1} \). Let \( l = (l_{ij}) (1 \leq i \leq m, 1 \leq j \leq n) \) be any system of rational integers. We define

\[ S_1(l, \gamma) = \sum_{X \mod Na_\gamma} e\left(S(\gamma C(X)) + \sum_{i,j} l_{ij} X_{ij}\right), \]

where \( X = (X_1, \ldots, X_m), X_i = \sum_j X_{ij} \omega_j \), and each \( X_{ij} \) runs through a complete system of residues modulo \( Na_\gamma \). We also put

\[ S_1((0), \gamma) = (Na_\gamma)^{m(n-1)} \sum_{X \mod Na_\gamma} e(S(\gamma C(X))) = (Na_\gamma)^{m(n-1)} S_\gamma. \]

\[ \square \]

**Lemma 2.3.** Let \( C(X) \) be a fixed cubic form in \( m \) variables which does not represent zero non-trivially, and \( \kappa \) a fixed number satisfying

\[ 0 < \kappa < \frac{1}{8} m. \]
Suppose $C(X)$ does not split with remainder $r$, where $r$ is the least integer satisfying

$$r \geq m - 4\kappa.$$ 

Then, for any $\gamma \in K$ and any system of rational integers $l = (l_{ij})$, we have

$$|S_1(l, \gamma)| < (N\alpha_\gamma)^{m\kappa}$$ 

(6) unless $N\alpha_\gamma$ is bounded above by a constant depending only on $\kappa$, the field $K$ and the form $C$. In particular, if $N\alpha_\gamma$ is large, we obtain

$$|S_\gamma| < (N\alpha_\gamma)^{m\kappa}.$$ 

(7)

Proof. We apply Lemma 2.2 (and the remark made at the end of that lemma) with the box $B = \{X : 0 \leq X_{ij} < 1\}$, $\gamma$ instead of $\alpha$, $N\alpha_\gamma$ instead of $P$, $(1/2n) - \delta$ instead of $\theta$, and $\kappa/n$ instead of $\kappa$. The conditions of that lemma are verified if $\delta$ is small enough. Hence if $N\alpha_\gamma$ is large enough and (6) does not hold, there is a non-zero integer $\mu$ in $(N\alpha_\gamma)^{1/n - \delta}B_0$ and $a\lambda \in d^{-1}$ such that

$$\mu\gamma - \lambda = \sum_{i=1}^{n} \epsilon_i \rho_i, \quad |\epsilon_i| < (N\alpha_\gamma)^{-3-\delta+1/n}.$$ 

But since $a_\gamma(\mu\gamma - \lambda) \subset d^{-1}$, $N\alpha_\gamma \epsilon_i$ must be a rational integer, and since

$$|N\alpha_\gamma\epsilon_i| < (N\alpha_\gamma)^{-2+1/n-\delta} < 1$$

for $N\alpha_\gamma$ large, it follows that $\epsilon_i = 0$ for $1 \leq i \leq n$, and $\mu\gamma \in d^{-1}$. By the definition of $a_\gamma$, we must have $\mu \in a_\gamma$, and $N\alpha_\gamma$ divides $N\mu$. But since

$$\mu \in (N\alpha_\gamma)^{1/n - \delta}B_0, \quad |N\mu| \leq A(N\alpha_\gamma)^{1-n\delta},$$

where $A$ depends only on $K$, which implies that for large $N\alpha_\gamma$, we must have $|N\mu| < N\alpha_\gamma$, and therefore $\mu = 0$, which is a contradiction. This proves the inequality (6). The inequality (7) follows from (6) since we have $S_1((0), \gamma) = (N\alpha_\gamma)^{m(n-1)}S_\gamma$. $\square$
3 The contribution of the major arcs

We shall continue to use the notations of the previous section. Further, we define \( \mathbb{R} \) to be the parallelepiped in \( K_R \) defined by

\[
\mathbb{R} = \left\{ x = \sum_{i=1}^{n} x_i\rho_i \mid 0 \leq x_i < 1 \right\}.
\]

For any \( \gamma \in K \), we define the ‘major arc’ \( B_\gamma \) to be the set of \( \alpha \in K_R \) such that if \( \beta = \alpha - \gamma = \sum_{i=1}^{n} \beta_i\rho_i \), we have \( |\beta_i| < P^{-2-\delta}(Na_\gamma)^{-1} \). We assert that if \( \gamma \neq \gamma' \) and \( Na_\gamma \leq P^{1-2\delta}, Na_{\gamma'} \leq P^{1-2\delta} \), \( B_\gamma \) and \( B_{\gamma'} \) cannot intersect. In fact, if they did intersect, we must have

\[
\gamma - \gamma' = \sum \gamma_i\rho_i, \quad |\gamma_i| < P^{-2-\delta} \left( (Na_\gamma)^{-1} + (Na_{\gamma'})^{-1} \right).
\]

But since \( a_\gamma a_{\gamma'} (\gamma - \gamma') \subset \mathfrak{d}^{-1} \), \( Na_\gamma Na_{\gamma'} \gamma_i \) must be a rational integer for all \( i \). Since \( |Na_\gamma Na_{\gamma'} \gamma_i| < P^{-2-\delta} (Na_\gamma + Na_{\gamma'}) < 2P^{1-2\delta}P^{-2-\delta} = 2P^{-1-3\delta} < 1 \), we must have \( \gamma_i = 0 \) and \( \gamma = \gamma' \).

Now let \( C(X) \) be a cubic form in \( m \) variables with coefficients integers in \( K \) and symmetric in all three indices. Our ultimate goal is to find, under suitable conditions on \( C \) and for a suitable choice of the box \( \mathcal{B} \), an asymptotic formula for the number \( \mathcal{N}(P) \) of solutions of the equation \( C(X) = 0 \) with \( X \) integral and \( X \in P \mathcal{B} \). If \( \alpha = \sum \alpha_i\rho_i \) denotes a general point of \( \mathbb{R} \) and \( d\alpha \) denotes the measure \( d\alpha_1, \ldots, d\alpha_n \), we have the following integral representation for \( \mathcal{N}(P) \):

\[
\mathcal{N}(P) = \int_{\mathbb{R}} E(\alpha)d\alpha. \quad (8)
\]

In this section, we shall establish under certain conditions on \( C \), and the box \( \mathcal{B} \) being suitably chosen, an asymptotic formula for the contribution to the integral on the right of (8) of the major arcs \( B_\gamma \) with
$N_{\alpha \gamma} \leq P^{1-2\delta}$. Because of the definition of $R$ and the periodicity of $E(\alpha)$ in the variables $\alpha_i$, the contribution of these major arcs is given by

$$\sum_{N_{\alpha} \leq P^{1-2\delta}} \sum_{\gamma \mod \frac{d}{a} \in B_\gamma} E(\alpha) d\alpha.$$ 

The main result of this section is the following:

**Lemma 3.1.** Let $C(X)$ be any cubic form in more than nine variables with integral coefficients in $K$ which does not represent zero non-trivially. Assume that (in the notation of §2) we have a uniform estimate of the form

$$|S_1(l, \gamma)| \leq (N_{\alpha \gamma})^{mn-\omega}$$

with $\omega > 2$. Then for $P$ tending to infinity suitably, and with a suitable choice of the box $B$, we have the following asymptotic formula

$$\sum_{N_{\alpha} \leq P^{1-2\delta}} \sum_{\gamma \mod \frac{d}{a} \in B_\gamma} E(\alpha) d\alpha = AP^{(m-3)n} + o(P^{(m-3)n}) \quad (0 < A < \infty).$$

The whole of this section is devoted to the proof of this lemma, which will be carried out in several steps.

Let $g(t_1, \ldots, t_p)$ be a function of $p$ variables defined in a parallelepiped $A_1^1 \leq t_i \leq A_2^2$, and let $Q$ be a subset $(r_1 < \cdots < r_q)$ of the set of integers $\{1, 2, \ldots, p\}$. We shall adopt the following conventions: $h_Q$ will denote an element of $\mathbb{Z}^Q$, that is, a set of integers $(h_{r_1}, \ldots, h_{r_q})$, and $|h_Q|$ the sum $\sum_{i=1}^q h_{r_i}$. If $s$ is a fixed integer, we shall denote the set $(s, \ldots, s)$ by $(s)_Q$. We shall write $\partial_Q^{h_Q} g$ in place of

$$\frac{\partial^{|h_Q|} g}{(\partial t_{r_1})^{h_{r_1}} \cdots (\partial t_{r_q})^{h_{r_q}}}.$$ 

If $a$ and $b$ are two integers, the symbol $\sum_{h_Q = a}^{b}$ will imply summation over all the $h_Q$ with $a \leq h_{r_i} \leq b (1 \leq i \leq q)$. An integral of the form
\[ \int_{A_Q^l}^{A_Q^2} g \, dt_Q \] will stand for the multiple integral

\[ \int_{A_{r_1}^1}^{A_{r_1}^2} \cdots \int_{A_{r_q}^1}^{A_{r_q}^2} g \, dt_{r_1} \cdots dt_{r_q}. \]

Finally, we shall mean by the symbol \([g(t_1, \ldots, t_p)]\Delta_Q\) the multiple difference expression

\[ \sum_{\lambda_i = 1 \text{ or } 2} (-1)^{\sum \lambda_i} g \left( t_1, \ldots, A_{r_1}^{\lambda_1}, \ldots, A_{r_2}^{\lambda_2}, \ldots, A_{r_q}^{\lambda_q}, \ldots \right). \]

With these notations, we can state

**Lemma 3.2.** Let \( f(x) = f(x_1, \ldots, x_k) \) be a function of \( k \) variables defined and continuous with all its partial derivatives up to order \( s \) in an open set containing the parallelepiped \( A_i \leq x_i \leq B_i (i = 1, \ldots, k) \), where we assume the \( A_i \) and \( B_i \) to be non-integral. Let \( z = (z_1, \ldots, z_k) \) be a set of \( k \) integers and let \( q \) be any integer \( \geq 1 \). Then we have

\[
\sum_{A_i < x < B_i} f(x_1, \ldots, x_k) = \sum_{\Phi} (-1)^{\mu} q^{\nu(s-1)-\lambda}
\times \left[ \sum_{h_j=0}^{s-1} q^{|h_j|} \prod_{j \in J} \psi_{h_j} \left( \frac{x_j - z_j}{q} \right) \prod_{i \in I} \psi_{s-1} \left( \frac{x_i - z_i}{q} \right) \sum_{\lambda_i = 1 \text{ or } 2} (-1)^{\sum \lambda_i} g \left( x_1, \ldots, A_{r_1}^{\lambda_1}, \ldots, A_{r_2}^{\lambda_2}, \ldots, A_{r_q}^{\lambda_q}, \ldots \right) \right]_{\Delta_j},
\]

where \( \Phi \) runs through all partitions of \([1, k]\) into three disjoint sets of integers

\[ I = \{i_1 < \ldots < i_{\lambda}\}, \quad J = \{j_1 < \ldots < j_\mu\} \quad \text{and} \quad K = \{k_1 < \ldots < k_v\}, \]

and for any integer \( h \geq 0 \), we write

\[ \psi_h(x) = (-1)^{h+1} \sum_{l=-\infty}^{\infty} \frac{e(lx)}{(2\pi l)^{h+1}}. \]

This lemma can be proved by induction on the number of variables, starting from Lemma 5.2 of [3]. We omit the details.

Note that \( \psi_h \) is bounded, being continuous and periodic.
LEMMA 3.3. Let $\xi_i = \sum_{j=1}^{n} \xi_{ij} \omega_j (i = 1, \ldots, m)$ and $\beta = \sum_{j=1}^{n} \beta_j \rho_j$ be elements of $K_R$, and let $h_{ij} (1 \leq i \leq m; 1 \leq j \leq n)$ be non-negative integers. Considering $e(S(\beta C(\xi)))$ as a function of the real variables $\xi_{ij}$ and $\beta_k$, we have identically

$$
\frac{\partial^h}{\partial_{\xi_{11}}^{h_{11}} \cdots \partial_{\xi_{mn}}^{h_{mn}}} (e(S(\beta C(\xi))) = e(S(\beta C(\xi))) \sum_{\frac{1}{h} \leq |\alpha| \leq h} \beta^\alpha \Phi_\alpha (\xi_{11}, \ldots, \xi_{mn}),
$$

where $\alpha$ runs through all multi-indices $(\alpha_1, \ldots, \alpha_n)$, $\alpha_i \geq 0$, such that $|\alpha| = \sum \alpha_i$ lies between $\frac{1}{3} h$ and $h$ ($h$ stands for $\sum h_{i,j}$) and $\Phi_\alpha$ is a homogeneous real polynomial in the $\xi_{ij}$ of degree $3|\alpha| - h$.

In particular, if $|\xi_{ij}| \leq B P$ and $|\beta_i| \leq \mu$, with $P^3 \mu > 1$, then the left side of the above identity is $\leq B' (P^2 \mu)^h$, where $B'$ depends only on $B$, $h_{ij}$, the coefficients of $C$ and the field $K$.

Proof. The first part can be proved easily by induction on $h = \sum_{i,j} h_{ij}$.

It follows that if $|\xi_{ij}| \leq B P$ and $|\beta_i| \leq \mu$, and $P^3 \mu > 1$, the left side is bounded in absolute value by a constant multiple of

$$
\sum_{\frac{1}{h} \leq v \leq h} \mu^v P^{3v-h} \sum_{\frac{1}{h} \leq v \leq h} \mu^{v_0} \left\{(P^3 \mu)^{h-v_0+1} - 1\right\} / (P^3 \mu - 1) \leq
$$

$$
P^{3v_0-h} \mu^{v_0} (P^3 \mu)^{h-v_0} = (P^2 \mu)^h,
$$

where $v_0$ denotes the least integer $\geq h/3$.

The lemma is proved. \hfill \Box

We shall now start on the proof of Lemma 3.1. Let $I = I(P)$ denote the expression on the left in Lemma 3.1, and $I_\gamma = \int_{B_\gamma} E(\alpha) \, d\alpha$, so that we have

$$
I = \sum_{N_0 \leq P^{1-2\delta}} \sum_{\gamma \mod p \cdot \beta-1} I_\gamma.
$$

For $\alpha$ in $B_\gamma$, we write $\alpha = \beta + \gamma$, so that we have

$$
\beta = \sum_i \beta_i \rho_i, \quad |\beta_i| < P^{-2-\delta}(N_0 \gamma)^{-1}.
$$
Suppose the box $P \mathcal{B}$ is defined by the inequalities $A_{ij} < X_{ij} < B_{ij}$, where we assume that the $A_{ij}$ and $B_{ij}$ are non-integral. We then have for $\alpha$ in $B_{\gamma}$,

$$
E(\alpha) = \sum_{Z_{ij}=1}^{N_{a_{\gamma}}} e(S(\gamma C(Z))) \sum_{X_{ij}=z_{ij}(N_{a_{\gamma}})} e(S(\beta C(X))),
$$

(9)

where $Z$ stands for $(Z_1, \ldots, Z_m)$, $Z_i = \sum_{j=1}^n Z_{ij}\omega_j$. Let $s$ be a fixed positive integer such that $s\delta > n + 1$. We substitute for the inner sum in the above expression from Lemma 3.2.

Still retaining the notations of Lemma 3.2, let $\Phi = I \cup J \cup K$ be any partition of the set of double indices $(i, j)$, $1 \leq i \leq m$, $1 \leq j \leq n$, with $K$ non-empty, that is $v > 0$, and let $h_J$ be a fixed element of $[0, s - 1]^J$. By Lemma 3.3, and using the fact that the $A_{ij}$ and $B_{ij}$ are $O(P)$, we deduce that the term arising from Lemma 3.2 corresponding to such a $\Phi$ and $h_J$ is

$$
\ll (N_{a_{\gamma}})^{v(s-1)-\lambda+|h_J|} (P^{-\delta}(N_{a_{\gamma}})^{-1})^{|h_J|+sv} P^{\lambda+v} = P^{-\delta(sv+|h_J|)} (P N_{a_{\gamma}}^{-1})^{\lambda+v},
$$

and since $P N_{a_{\gamma}}^{-1} \geq P^{2\delta} > 1$, and $v \geq 1$, the above expression is

$$
\ll P^{-\delta s}(P(N_{a_{\gamma}})^{-1})^{mn}. \text{ Summation over the } Z_{ij} \text{ and integration over } B_{\gamma} \text{ gives the contribution of the terms corresponding to a fixed } \Phi \text{ and } h_J \text{ to } I_{\gamma} \text{ to be } \ll P^{mn-\delta s}(P^{-2+\delta}N_{a_{\gamma}})^{-n}, \text{ and hence the contribution to } I \text{ is }
$$

$$
P^{(m-2-\delta)n-s\delta} \sum_{N_{a} \leq P^{1-2\delta}} (N_{a})^{1-n} \ll P^{(m-2-\delta)n-(s+2)\delta+1} \ll P^{mn-3n-\delta}
$$

since $s\delta > n + 1$. This takes care of the terms arising from Lemma 3.2 corresponding to the partitions $\Phi$ for which $K$ is non-empty. For the estimation of the remaining terms, we have to make a proper choice of the box $\mathcal{B}$. The possibility of this choice is given by the next

**Lemma 3.4.** Let $C(\xi) = \sum_{i=1}^n C_i(\xi_{11}, \ldots, \xi_{mm})\omega_i$, where each $C_i$ is a cubic form with rational integral coefficients in the variables $\xi_{ij}$. We
assume that \( m > 1 \) and that \( C(\xi) \) does not represent zero non-trivially. Then there exists a box

\[
\mathcal{B} = \{ \xi \in (K_R)^m | a_{ij} < \xi_{ij} < b_{ij} \}
\]

in \((K_R)^m\) such that the following conditions hold:

(a) \( a_{ij} = m_{ij}/2N, b_{ij} = n_{ij}/2N, \) where \( m_{ij} \) and \( n_{ij} \) are odd integers, and \( N \) a positive integer. We have \( b_{ij} - a_{ij} < 1 \);

(b) there is a point \( \xi^0 = (\xi^0_{ij}) \) in \( \mathcal{B} \) and a set \( R \) of \( n \) couples \((p_j, q_j)\) \((j = 1, \ldots, n)\) such that we have

\[
C_i(\xi^0) = 0 \quad (i = 1, \ldots, n),
\]

\[
\det \left| \frac{\partial C_i}{\partial \xi_{(p_j, q_j)}}(\xi^0) \right| \neq 0.
\]

Let \( T \) denote the set of couples \((i, j)(1 \leq i \leq m, \ 1 \leq j \leq n)\) not belonging to \( R \);

(c) for any subset \( S \) of \( R \), there is a subset \( S' \) of \( \{1, 2, \ldots, n\} \) such that for any fixed values of \( \xi_{ij} \) for \((i, j) \in R - S\) satisfying \( a_{ij} < \xi_{ij} < b_{ij} \), the mapping \((\xi_T, \xi_S) \rightarrow (\xi_T, \eta_{S'})\) defined by \( \eta_i = C_i(\xi) \) is an analytic isomorphism of the domain defined by \( a_T < \xi_T < b_T, \ a_S < \xi_S < b_S \) onto a domain in the \((\xi_T, \eta_{S'})\) space containing the domain defined by \( a_T < \xi_T < b_T, \ |\eta_{S'}| < \epsilon(\xi_T, \xi_S, \ \text{etc.}, \ \text{stand for the set of variables } \xi_{ij} \text{ with } (i, j) \in T, S, \ \text{etc.}, \ \text{respectively}; \ \epsilon \text{ is some fixed positive quantity}) \).

In order not to interrupt our discussion, we shall postpone the proof of this lemma to the end of this section.

Let us now turn to the estimation of those terms arising from the substitution from Lemma 3.2 in (9), corresponding to a fixed partition \( \Phi \) of the double-indices into two sets \( I \) and \( J \) (in the notations of the same lemma) with \( J \) non-empty, and to a fixed \( h_J \). Let \( I = \{(i_1, j_1), \ldots, (i_p, j_p)\} \) and \( J = \{(i'_1, j'_1), \ldots, (i'_q, j'_q)\} \), with \( q > 0 \), and
let \( h_J = (h_{i_1'j_1'}, \ldots, h_{i_q'j_q'}) \). Such a term when summed over the \( Z_{ij} \)
and integrated over \( B_\gamma \) gives

\[
\pm (N_{\alpha_\gamma})^{-p+h} T \sum_{\frac{1}{2}h \leq |\alpha| \leq h} \int_{A_I}^{B_I} \Phi_\alpha(\xi) \left\{ \int_{|\beta| < \mu} \beta^\alpha e(S(\beta C(\xi))) d\beta \right\} d\xi_1,
\]

(10)

where the \( \Phi_\alpha \) are as in Lemma 3.3, each one of the variables

\[ \xi_{i_1'j_1'}, \ldots, \xi_{i_q'j_q'} \]

is fixed at a corresponding \( A_{ij} \) or \( B_{ij} \), \( \mu \) stands for the expression

\[ P^{-2-\delta} (N_{\alpha_\gamma})^{-1}, \]

and \( T \) is defined by the equation

\[
T = \sum_{Z_{ij}=1}^{N_{\alpha_\gamma}} e(S(\gamma C(Z))) \psi_{h(i_1'j_1')} \left( \frac{\xi_{(i_1'j_1')} - Z_{(i_1'j_1')}}{N_{\alpha_\gamma}} \right) \ldots \psi_{h(i_q'j_q')} \left( \frac{\xi_{(i_q'j_q')} - Z_{(i_q'j_q')}}{N_{\alpha_\gamma}} \right).
\]

Let us put

\[ S_{r}(x) = \int_{-x}^{x} t^r e(t) dt. \]

Then (10) becomes

\[
\pm (N_{\alpha_\gamma})^{-p+h} T \sum_{\frac{1}{2}h \leq |\alpha| \leq h} \int_{A_I}^{B_I} \Phi_\alpha(\xi) \prod_{r=1}^{n} S_{\alpha_r} \left( \frac{\mu C_r(\xi)}{(C_r(\xi))^{\alpha_r+1}} \right) d\xi_1.
\]

If we change \( \xi \) (including the fixed \( \xi_J \)) to \( P\xi \), and use the fact that \( \Phi_\alpha \) is homogeneous of degree \( 3|\alpha| - h \), the above expression becomes

\[
\pm (N_{\alpha_\gamma})^{-p+h} T \sum_{\frac{1}{2}h \leq |\alpha| \leq h} P^{p-3n-h} \int_{a_I}^{b_I} \Phi_\alpha(\xi) \prod_{r=1}^{n} S_{\alpha_r} \left( \frac{P^3 \mu C_r(\xi)}{(C_r(\xi))^{\alpha_r+1}} \right) d\xi_1.
\]

Now let \( S = R \cap I \) and \( S' \) the subset of \( \{1, 2, \ldots, n\} \) corresponding to \( S \) by Lemma 3.4(c); let \( T' = I - R \cap I = T \cap I \). For any fixed values of
$\xi_{R-1}$ in the respective intervals, the mapping $\xi_I = (\xi_S, \xi_{T'}) \to (\eta_{S'}, \xi_{T'})$ defined by $\eta_t = C_I(\xi)$ is an analytic isomorphism of the parallelepiped $a_I < \xi_I < b_I$ onto a domain in the $(\eta_{S'}, \xi_{T'})$ space, whose Jacobian we shall denote by $J(\xi_{T'}, \eta_{S'})$. Writing $\phi$ for $P^3 \mu$, the above expression then transforms into

$$
\pm (Na_y)^{-p+h} T \sum_{\frac{1}{2} \leq |\alpha| \leq h} P^{p-3n-h} \times \int \prod_{r \in S'} \frac{S_{ar}(\phi \eta_r)}{\eta_r^{\alpha_r+1}} \left\{ \int \mathcal{D}(\eta_{r'}) \prod_{r' \not\in S'} \frac{S_{ar}(\phi C_r(\xi))}{(C_r(\xi))^{\alpha_r+1}} \Phi_\alpha(\xi)|J(\xi_{T'}, \eta_{S'})|d\xi_{T'} \right\} d\eta_{S'},
$$

where the integration with respect to $\eta_{S'}$ is over a certain bounded domain and for every $\eta_{S'}$ in this domain, $\mathcal{D}(\eta_{S'})$ is a uniformly bounded domain in the $\xi_{T'}$-space. It is easy to see (by direct evaluation, or otherwise), that we have $S_p(x) \ll x^p$ for all $x$ and $S_p(x) \ll x^{p+1}$ for $x \ll 1$. Since $\Phi_\alpha(\xi)$ and $J$ are absolutely and uniformly bounded on any bounded domain, the above integral is

$$
\ll \phi \sum_{r \not\in S'} (\alpha_r + 1) \prod_{r \in S} \left\{ \int_{-A}^{A} \frac{S_{ar}(\phi \eta_r)}{\eta_r^{\alpha_r+1}} |d\eta_r| \right\} \ll \phi^{|\alpha|+n_0} \log^n \phi \ll \phi^{|\alpha|+n_0} \log^n P,
$$

where $n_0$ denotes the number ($n$ – number of elements in $S$). Hence (10) is bounded by

$$
|T| (P(Na_y)^{-1})^{p-h} P^{-3n} (P^3 \mu)^{n_0 + |\alpha|} \log^n P = |T| (P(Na_y)^{-1})^{p-h+n_0 + |\alpha|} \quad P^{-3n-\delta(n_0 + |\alpha|)} \log^n P \ll |T| (P(Na_y)^{-1})^{p+n_0} P^{-3n-\delta n_0}.
$$

We shall now estimate $|T|$. We have for any integer $k \geq 0$ and any integer $Q \geq 0$,

$$
\psi_k(x) = (-1)^{k+1} \sum_{l=-Q}^{Q} \frac{e(lx)}{(2\pi il)^{k+1} + R_Q},
$$

where the ′ over the summation sign means that there is no term corresponding to $l = 0$, and

$$
|R_Q| \leq \frac{1}{Q^{k+1}||x||},
$$
We shall now assume that $P$ varies through odd multiples of the integer denoted by $N$ in Lemma 3.4(a). It follows that for $Z_{ij}$ integral and $\xi_{ij} = Pa_{ij}$ or $Pb_{ij}$,

$$\left| \frac{\xi_{ij} - Z_{ij}}{Na_{\gamma}} \right| \geq \frac{1}{Na_{\gamma}},$$

and on substituting from the above expression for $\psi_k(x)$ into $T$, with $Q = (Na_{\gamma})^{mn+1}$, we obtain

$$|T| \leq \left( \frac{1}{2\pi} \right)^{h+q} (Na_{\gamma})^{mn+1} \sum_{l_1, \ldots, l_q = - (Na_{\gamma})^{mn+1}} |l_1|^{-h_{(l_1', l_1')}^{-1}} \cdots |l_q|^{-h_{(l_q', l_q')}^{-1}} \times \left| \sum_{Z_{ij} = 1}^{Na_{\gamma}} e(S(\gamma C(Z))) + \frac{l_1 Z_{(l_1', l_1')} + \cdots + l_q Z_{(l_q', l_q')}}{Na_{\gamma}} \right|$$

and by our assumption in Lemma 3.1, we get

$$|T| \ll (Na_{\gamma})^{mn-\omega}(\log Na_{\gamma})^{mn} \ll (Na_{\gamma})^{mn-\omega'}$$

for any fixed $\omega' < \omega$. Substituting in our earlier estimate for (10), summing over all $\gamma \mod d^{-1}$ with $a_{\gamma} = a$ and finally summing over all $a$ with $Na \leq P^{1-2\delta}$ we deduce that the total contribution to $I$ of the terms arising from a partition $\Phi$ for which $J$ is non empty is

$$\ll P^{p+n_0-3n-\delta n_0} \log^n P \sum_{Na < P^{1-2\delta}} (Na)^{mn-p-n_0-\omega'+1}$$

$$\ll P^{p+n_0-3n-\delta n_0} \log^{n+1} P(1 + P^{mn-p-n_0-\omega'+2}).$$

Since by definition $n_0 \leq q$, we must have $p + n_0 \leq p + q = mn$, and if $p + n_0 = mn$, we must have $n_0 = q \geq 1$. Hence if we put $\rho = \min(\delta, \omega' - 2)$, the above expression is $O(P^{mn-3n-\rho \log^{n+1} P})$ which is $o(P^{(m-3)n})$.

To complete the proof of Lemma 3.1, it only remains to estimate the main term which arises from the partition $\Phi$ for which $J$ and $K$ are empty, so that $I$ is the set of all couples $(i, j)$, $1 \leq i \leq m$, $1 \leq j \leq
A calculation exactly similar to the one made above shows that the contribution of this term to $I_γ$ is

$$
(Na_γ)^{mn}S_1((0), γ) \int_{B} \left\{ \int_{-μ}^{μ} e(S(BC(ξ)))dβ \right\} dξ \\
= P^{(m-3)n}(Na_γ)^{-1}S_γ \int_{B} \left( \prod_{r=1}^{n} \frac{\sin φC_r(ξ)}{C_r(ξ)} \right) dξ 
$$

with the notations of the previous paragraph. Changing from $(ξ_1, ξ_T)$ to $(η, ξ_T)$, the above becomes

$$
P^{(m-3)n}(Na_γ)^{-1}S_γ \int_{B} dξ_T \left\{ \int_{D(ξ_T)} \prod_{r=1}^{n} \frac{\sin φη_r}{η_r} |J(ξ_T, η)|dη \right\},
$$

where $J(ξ_T, η)$ denotes the Jacobian of the above transformation and $D(ξ_T)$ is a certain uniformly bounded domain in the $η$-space which always contains the domain $|η| < ε$, by Lemma 3.4(c).

Now split the domain $D(ξ_T)$ into $2^n$ parts in each of which a certain subset of the variables $η$ remain $>$ $ε$, while the others remain $<$ $ε$. We shall show that on any of these subdomains on which at least one $η_i$ remains $>$ $ε$, the integral over this subdomain of $\prod_{r=1}^{n} \eta_r^{-1} \sin φη_r J(ξ_T, η)$ tends to zero uniformly with respect to $ξ_T$ as $φ$ tends to $∞$. Assume for instance that $η_n > ε$ in such a subdomain. We rewrite the integral of the above function as a repeated integral

$$
\int \frac{\sin φη_1}{η_1}dη_1 \int \frac{\sin φη_2}{η_2}dη_2 \ldots \int \frac{\sin φη_n}{η_n}dη_n.
$$

Now, since the boundary of $D(ξ_T)$ consists of algebraic hypersurfaces, it is easy to see that the line through any point $(η_1, \ldots, η_n)$ in $D(ξ_T)$ parallel to the $η_n$-axis meets the boundary of $D(ξ_T)$ in a uniformly bounded number of points. Hence the last integral with respect to $η_n$ is over a uniformly bounded number of intervals in $η_n$ on all of which intervals we have $|η_n| > ε$. Since $|J(ξ_T, η)|/η_n$ is uniformly bounded and of uniformly bounded variation with respect to $η_n$ in any bounded interval on
which $|\eta_n| > \epsilon$, we deduce that the above repeated integral is

$$\leq \frac{1}{\phi} \left\{ \int_{-A}^{A} \left| \frac{\sin \phi \eta}{\eta} \right| d\eta \right\}^{n-1} \leq \frac{\log^{n-1} \phi}{\phi}$$

$\to 0$ uniformly as $\phi \to \infty$, and since $\phi = P^{3} \mu = P^{1-\delta} (Na_{\gamma})^{-1} \geq P^{\delta}$, also as $P \to \infty$. Hence the ‘main term’ of $I_{\gamma}$ is

$$P^{mn-3n}(Na_{\gamma})^{-m} S_{\gamma} \left[ \int_{aT}^{bT} d\xi T \left\{ \int_{|\eta|<\epsilon} \prod_{r} \frac{\sin \phi \eta_{r}}{\eta_{r}} |J(\xi T, \eta)| d\eta \right\} + o(1) \right].$$

Now since $|J(\xi T, \eta)|$ (being always equal to $J(\xi T, \eta)$ or to $-J(\xi T, \eta)$ in $D(\xi T)$) is analytic in $\eta$, we may write

$$|J(\xi T, \eta)| = |J(\xi T, 0)| + \sum_{i} \eta_{i} \psi_{i}(\xi T, \eta),$$

where the $\psi_{i}$ are again analytic. It can be shown by an argument similar to the one used above that

$$\int_{|\eta|<\epsilon} \prod_{r} \frac{\sin \phi \eta_{r}}{\eta_{r}} \eta_{i} \psi_{i}(\xi T, \eta) d\eta$$

$\to 0$ as $P \to \infty$ for all $i$ uniformly. Hence the main term reduces to

$$P^{(m-3)N} (Na_{\gamma})^{-m} S_{\gamma} \left\{ \int_{aT}^{bT} |J(\xi T, 0)| d\xi T \left( \int_{-\epsilon}^{\epsilon} \frac{\sin \phi x}{x} dx \right)^{n} + o(1) \right\}$$

$$= P^{(m-3)N} (Na_{\gamma})^{-m} S_{\gamma} (A + o(1)),$$

where

$$A = \pi^{n} \int_{aT}^{bT} |J(\xi T, 0)| d\xi T > 0$$

and $o(1)$ tends to zero uniformly as $P \to \infty$.

On summing over the $\gamma$ for which $a_{\gamma} = a$ and summing over all $a$ with $Na \leq P^{1-2\delta}$, we see that the main term in $I$ is

$$AP^{(m-3)N} \sum_{\gamma \mod d^{-1}} (Na_{\gamma})^{-m} S_{\gamma} + o \left( P^{(m-3)N} \sum_{\gamma \mod d^{-1}} (Na_{\gamma})^{-m} |S_{\gamma}| \right).$$
Since \((Na_\gamma)^{m(n-1)}S_\gamma = S_1((0), \gamma)\), the assumption of Lemma 4.1 implies that
\[ S_\gamma = O((Na_\gamma)^{m-\omega}), \]
with \(\omega > 2\), and hence the series
\[ r = \sum_{\gamma \mod d^{-1}} (Na_\gamma)^{-m}S_\gamma \]
converges absolutely.

Hence we obtain finally that
\[ I = Arp^{(m-3)n} + o(p^{(m-3)n}), \]
and Lemma 3.1 will be proved completely if we can show that \(r > 0\). This will be our next task.

**Lemma 3.5.** Under the assumptions of Lemma 3.1, we have
\[ x > 0. \]

**Proof.** It can be shown by standard arguments that if \(\gamma_1\) and \(\gamma_2\) are elements of \(K\) different from zero such that \(a_{\gamma_1}\) and \(a_{\gamma_2}\) are coprime, we have \(S_{\gamma_1}S_{\gamma_2} = S_{\gamma_1 + \gamma_2}\). For any prime ideal \(p\) of \(O\), we define
\[ \chi(p) = 1 + \sum_{p \geq 1} (Np)^{-mp} \sum_{\gamma \mod d^{-1}, \ a_{\gamma} = p^m} S_\gamma; \]
this series is absolutely convergent, since it is majorized by the absolute values of the terms of the series for \(r\), and we deduce easily that
\[ r = \prod_p \chi(p), \]
the product being absolutely convergent. To prove the lemma, it is therefore sufficient to show that \(\chi(p) > 0\) for all \(p\).

Now, let \(M(p^N)\) denote for any integer \(N\) the number of solutions of the congruence
\[ C(X) \equiv O(p^N), \]
when the $X_i$ run through a complete system of residues modulo $p^N$. Then it can be shown easily that

$$\sum_{\gamma \mod b^{-1}}^N (Np)^{-mp} S_{\gamma} = (Np)^{-m} M(p^N),$$

and therefore

$$\chi(p) = \lim_{N \to \infty} (Np)^{-N(m-1)} M(p^N).$$

Let $K_p$ denote the $p$-adic completion of the field $K$. Then it is well known (and is easily established) that if the form $C(X)$ has a non-trivial non-singular zero in $K_p$, then

$$\lim_{N \to \infty} (Np)^{-N(m-1)} M(p^N) > 0.$$  

From the fact that $C(X)$ does not represent zero non-trivially it follows that it is non-degenerate, i.e. we cannot reduce it to a form in a fewer number of variables by making a non-singular linear change of variable in $C(X)$. But for a non-degenerate cubic form over a $p$-adic field in more than 9 variables, the existence of a non-singular zero has been proved by several authors (see, for instance, (2)).

This finishes the proof of Lemma 3.5. \qed

Lemma 3.1 is therefore completely proved, except for the proof of Lemma 3.4, which we shall now give.

**Proof of Lemma 3.4.** It is enough to prove the existence of a point $\xi^0$ in $(K_R)^m$, $\xi^0 \neq 0$, such that

$$C_i(\xi^0) = 0 \quad (i = 1, \ldots, n), \quad \text{Rank} \left\| \frac{\partial C_i}{\partial \xi(j,k)}(\xi^0) \right\| = n.$$  

For, once we have found such a $\xi^0$, we can find a box $B$ satisfying the conditions $(a)$, $(b)$ and $(c)$ by the implicit function theorem (to get $(a)$, we use the fact that the rational numbers of the form $a/2N$, where $a$ is an odd integer and $N$ a positive integer, are dense in $R$). We are therefore
reduced to proving the existence of a real non-trivial, non-singular zero of the variety defined by the equations $C^i(\xi) = 0 (1 \leq i \leq n)$.

Let $\chi^{(1)}, \ldots, \chi^{(r_1)}$ denote the distinct isomorphisms of $K$ into $R$, and $\chi^{(r_1+1)}, \ldots, \chi^{(n)}$ the distinct isomorphisms of $K$ into $C$ such that $\chi^{(r_1+p+r)} = \tilde{\chi}^{(r_1+p)}(1 \leq p \leq r_2)$. For any $x \in K$, we shall put $\chi^{(i)} = \chi^{(i)}(x)$, and $C^{(i)}(X)$ will denote the form deduced from $C(X)$ by applying $\chi^{(i)}$ to its coefficients. For $1 \leq p \leq r_2$, we put

$$C^{(r_1+p)}(X + iY) = C^{(r_1+p)}_1(X, Y) + iC^{(r_1+p)}_2(X, Y),$$

where $C^{(r_1+p)}_1$ and $C^{(r_1+p)}_2$ are forms in the variables $X = (X_{ij})$ and $Y = (Y_{ij})$ with real coefficients.

If we now make the following real non-singular transformation of the variables $\xi_{ij}$,

$$\eta^{(p)}_{i} = \sum_{j} \xi_{ij}\omega^{(p)}_{j} \quad (1 \leq p \leq r_1),$$

$$\begin{align*}
\eta^{(r_1+p)}_{i} &= \sum_{j} \xi_{ij}\omega^{(r_1+p)}_{j} \\
\eta^{(r_1+p)}_{i} &= \sum_{j} \xi_{ij}\omega^{(r_1+p)}_{j}
\end{align*} \quad (1 \leq p \leq r_2),$$

where $\omega^{(r_1+p)}_{j}$ and $\omega^{(r_1+p)}_{j}$ stand for the real and imaginary parts of $\omega^{(r_1+p)}_{j}$, the variety in the $\xi$-space defined by $C_i(\xi) = 0 (i = 1, \ldots, n)$ gets transformed into the variety in the $\eta$-space defined by the equations

$$\begin{align*}
C^{(p)}(\eta^{(p)}_{1}, \ldots, \eta^{(p)}_{m}) &= 0 \quad (1 \leq p \leq r_1), \\
C^{(r_1+p)}_1(\eta^{(r_1+p)}_{1}, \ldots, \eta^{(r_1+p)}_{m}, \eta^{(r_1+p)}_{1}, \ldots, \eta^{(r_1+p)}_{m}) &= 0 \\
C^{(r_1+p)}_2(\eta^{(r_1+p)}_{1}, \ldots, \eta^{(r_1+p)}_{m}, \eta^{(r_1+p)}_{1}, \ldots, \eta^{(r_1+p)}_{m}) &= 0
\end{align*} \quad (1 \leq p \leq r_2),$$

and is therefore the product of the varieties $V_p$ defined by

$$C^{(p)}(X) = 0 (1 \leq p \leq r_1)$$
and the varieties $W_q$ defined by $C_1^{(r_1+q)}(X,Y) = 0$, $C_2^{(r_1+q)}(X,Y) = 0(1 \leq q \leq r_2)$. Hence it is enough to find a real non-trivial, non-singular point on each of the varieties $V_p, W_q$. It is shown in [3], Lemma 6.1 that such a point exists on each $V_p$. As for $W_q$, it is easy to see that if $Z = X + iY$ is a non-singular zero of $C^{(r_1+q)}(Z) = 0$, where $X$ and $Y$ are real, $(X,Y)$ is a real non-singular zero of $W_q$. This concludes the proof of Lemma 3.4.

We make a final remark concerning the exponential sum $S_1(l, \gamma)$. Suppose $C(X)$ and $C'(Y)$ are two cubic forms in the disjoint sets of variables $X$ and $Y$, and $S_1(l, \gamma)$ and $S'_1(l', \gamma)$ are the corresponding sums. Then if $S''_1((l, l'), \gamma)$ denotes the sum corresponding to the form $C(X) + C'(Y)$ in the variables $X$ and $Y$, we have clearly

$$S''_1((l, l'), \gamma) = S'_1(l, \gamma)S'_1(l', \gamma)$$

and therefore the uniform estimates

$$|S_1(l, \gamma)| \leq (Na_\gamma)^{m-\omega}, \quad |S'_1(l', \gamma)| \leq (Na_\gamma)^{m'-\omega'}$$

imply the uniform estimate $|S''_1((l, l'), \gamma)| \leq (Na_\gamma)^{(m+m')n-(\omega+\omega')}$, where $m$ and $m'$ are the number of variables $X$, and $Y$ respectively. We shall make use of this remark later.

4 Proof of the theorem

We shall denote by $m$ the set of points of $\mathcal{R}$ which do not belong to the major arcs, i.e. $m = \mathcal{R} - \bigcup_{Na_\gamma \leq P^{1-2\delta}} B_\gamma$. For any $\theta$ with $0 < \theta < 1$, we shall denote by $m_\theta$ the set of points $\alpha \in m$ for which there does not exist an integer $\lambda \in P^{2\theta+\delta} B_0$, $\lambda \neq 0$, and a $\mu \in \mathbb{B}^{-1}$ such that we have

$$\lambda \alpha - \mu = \sum \epsilon_i \rho_i, \quad |\epsilon_i| < P^{-3+2\theta+\delta}.$$ We shall show that if $\theta < \{1 - \delta(n + 2)\}/2n$ and $P$ is large enough, $m_\theta = m$. Suppose on the contrary that there exists an integer $\lambda$ and an
element \( \mu \in \mathfrak{a}^{-1} \) satisfying the above conditions. Putting \( \gamma = \mu/\gamma \), we have clearly \( \lambda \in \alpha, \) and therefore

\[
N\alpha_\gamma \leq N\lambda \leq P^{n(2\theta+\delta)},
\]

and by our assumption on \( \theta \), it follows that if \( P \) is large enough, \( N\alpha_\gamma \leq P^{1-2\delta} \). Moreover, we have

\[
\alpha - \gamma = \alpha - \mu/\lambda = \lambda^{-1} \sum_{i=1}^{n} \epsilon_i \rho_i = \sum_{i=1}^{n} \epsilon_i \left( \sum_{j=1}^{n} \alpha_{ij} \rho_j \right) = \sum_{j=1}^{n} (\sum_{i} \alpha_{ij} \epsilon_i) \rho_j = \sum_{j=1}^{n} \beta_j \rho_j,
\]

where \( (a_{ij}) \) is the regular representation matrix of \( \lambda^{-1} \) with respect to the basis \( \rho_1, \ldots, \rho_n \) of \( K \) over \( \Gamma \). Hence it follows that \( (a_{ij}) \) is the inverse of the regular representation matrix of \( \lambda \) with respect to the same basis. Hence for any \( i, j(1 \leq i \leq n, \ 1 \leq j \leq n) \), we have

\[
a_{ij} \ll P^{(n-1)(2\theta+\delta)}(N\lambda)^{-1},
\]

\[
|\beta_j| \ll P^{-3+2\theta+\delta} + (n-1)(2\theta+\delta)(N\lambda)^{-1} \ll P^{-3+n(2\theta+\delta)}(N\alpha_\gamma)^{-1},
\]

and therefore for \( P \) large, \( |\beta_j| \ll P^{-2-2\delta}(N\alpha_\gamma)^{-1} \), which shows that \( \alpha \) lies on the ‘major arc’ \( B_\gamma \), and hence cannot be in \( m \). Our contention is proved.

For any \( \theta \) with \( 0 < \theta < 1 \), we shall denote by \( \mathcal{E}(\theta) \) the set of points \( \alpha \in \mathcal{R} \) for which there exists an integer \( \lambda \in P^{2\theta+\delta}B_0, \lambda \neq 0, \) and a \( \mu \in \mathfrak{a}^{-1}, \) such that

\[
\lambda \alpha - \mu = \sum \epsilon_i \rho_i, \quad |\epsilon_i| < P^{-3+2\theta+\delta}.
\]

We have

\[m - m_\theta = m \cap \mathcal{E}(\theta) \subset \mathcal{E}(\theta).
\]

We want to estimate the measure of \( \epsilon(\theta) \). For a fixed \( \lambda \) and \( \mu \), the set of \( \alpha \) having the above property is equal to \( (P^{-3+2\theta+\delta})^n(N\lambda)^{-1} \), since multiplication by \( \lambda \) multiplies the \( n \)-dimensional measures of sets by \( N\lambda \).
Since for any fixed integer $\lambda$, there correspond at most $O(N\lambda)$ elements $\mu \in \mathfrak{b}^{-1}$ for which there exists an $\alpha \in \mathfrak{R}$ satisfying the above inequalities with respect to this $\lambda$ and $\mu$, we obtain

$$|\mathcal{E}(\theta)| \leq \sum_{\lambda \in P^{2\theta+\delta}B_0} (P^{-3+2\theta+\delta})^n (N\lambda)^{-1} N\lambda \leq (P^{-3+4\theta+2\delta})^n.$$ 

We need two lemmas which give estimates for exponential sums involving a single cube.

**Lemma 4.1.** For $\alpha \in \mathfrak{R}$, $B$ a fixed box in $K_\mathfrak{R}$, $d$ an integer in $K$ and $P > 1$, we define

$$T_d(\alpha) = \sum_{X \in PB} e(S(\alpha dX^3)).$$

Then for $\alpha \in \mathfrak{m}_\theta$ and $P$ large, we have

$$|T_d(\alpha)| < P^{(1-\frac{4}{3}\theta)n}.$$ 

**Proof.** We apply Lemma 1.3 of §1 to $\Gamma(X) = \alpha dX^3$, with $\theta + \frac{1}{2}\delta$ instead of $\theta$ and $\kappa = \frac{1}{4}\theta$; we have $B_1(X,Y) = 6\alpha dXY$. We conclude that if the above estimate for $|T_d(\alpha)|$ is not valid, and $P$ large enough, there exist $X \in P^{\theta+\frac{1}{2}\delta}B_0$, $Y \in P^{\theta+\frac{1}{2}\delta}B_0$, neither zero, and $\mu \in \delta^{-1}\mathfrak{b}$ such that

$$6\alpha dXY - \mu = \sum_{i=1}^n \epsilon_i \rho_i,$$

$$|\epsilon_i| < P^{-3+2\theta+\frac{2}{3}\delta} < P^{-3+2\theta+\delta}.$$ 

For, the number of solutions of these inequalities is, by Lemma 1.3, $\gg \{P^{\theta+\frac{2}{3}\delta}(\log P)^{-1}\}^n$ and the number of solutions with $X$ or $Y$ zero is $\ll P^{n\theta}$.

But now, $6dXY$ is a non-zero integer and is in $P^{2\theta+\delta}B_0$ for $P$ large. This contradicts the fact that $\alpha \in \mathfrak{m}_\theta$, proving the lemma.

**Lemma 4.2.** Let $\gamma \in K$ and let $l_1, \ldots, l_n$ be any set of rational integers. Then if

$$X = \sum_{i=1}^n X_i \omega_i$$

runs through a complete system of residues mod \( N_{\gamma} \), we have for any \( \epsilon > 0 \),

\[
\left| \sum_{X \mod N_{\gamma}} e \left( S \left( \gamma dX^3 + \frac{l_1 X_1 + \ldots + l_n X_n}{N_{\gamma}} \right) \right) \right| \ll (N_{\gamma})^{n - \frac{1}{3} + \epsilon}.
\]

**Proof.** Let \( a = \gcd \left( \gamma, \frac{\sum l_i \rho_i}{N_{\gamma}} \right) \) and \( b = (1, ab)^{-1} \).

It is clear that \( a_{\gamma} \) divides \( b \), which in turn divides \( N_{\gamma} \). The above sum can be rewritten as

\[
\sum_{X \mod N_{\gamma}} e \left( S \left( \gamma dX^3 + \frac{\sum l_i \rho_i}{N_{\gamma}} X \right) \right) = \frac{(N_{\gamma})^n}{Nb} \sum_{X \mod b} e \left( S \left( \gamma dX^3 + \frac{\sum l_i \rho_i}{N_{\gamma}} X \right) \right).
\]

By Hua (4), the latter sum is \( \ll (Nb)^{\frac{2}{3} + \epsilon} \), and therefore for the sum we started with, we obtain

\[
| \sum | \ll (N_{\gamma})^n (Nb)^{\frac{1}{3} + \epsilon} \ll (N_{\gamma})^{n - \frac{1}{3} + \epsilon}
\]

since \( Nb \geq N_{\gamma} \). Lemma 4.2 is proved. \( \square \)

**LEMMA 4.3.** Let

\[ C(X, Y) = C^{(1)}(X_1, \ldots, X_{m_1}) + d_1 Y_1^3 + \ldots + d_t Y_t^3 \]

be a cubic form with symmetric integral coefficients in \( K \) which does not represent zero. We assume moreover that

(i) \( 0 \leq t \leq 8 \);

(ii) if \( r \) is the least integer > \( 7 - \frac{1}{2} t \), then \( m_1 \geq 2(r + 1) \).

Then \( C^{(1)}(X) \) splits with remainder \( m_1 - r \).

**Proof.** Assuming that \( C^{(1)}(X) \) does not split with remainder \( m_1 - r \), we shall show that \( C(X, Y) \) represents zero non-trivially.
For any $\gamma \in K$, and any sets of rational integers

$$l = (l_{ij}) \quad (1 \leq i \leq m_1, \ 1 \leq j \leq n)$$

and

$$l' = (l'_{kj}) \quad (1 \leq k \leq t, \ 1 \leq j \leq n),$$

let $S_1^{(1)}(l, \gamma)$ and $S_1(l, l', \gamma)$ be the exponential sums associated to the forms $C^{(1)}$ and $C$ respectively. We may apply Lemma 2.3 to the form $C^{(1)}$ with $\kappa = \frac{1}{4}(r + 1) - \delta$, since

$$0 < 8\kappa = 2(r + 1) - 8\delta < m_1$$

and $C^{(1)}(x)$ does not split with remainder $m_1 - r$ which is the least integer

$$\geq m_1 - 4\kappa = m_1 - r - 1 + 4\delta.$$ 

Hence we obtain

$$|S_1^{(1)}(l, \gamma)| \ll (Na_\gamma)^{m_1n - \frac{1}{4}(r+1)+\delta}.$$ 

This, coupled with Lemma 4.2 and the remark made at the end §3, gives

$$|S_1(l, l', \gamma)| \ll (Na_\gamma)^{(m_1+t)n - \frac{1}{4}(r+1)-\frac{1}{3}t+2\delta}$$

and

$$\frac{1}{4}(r + 1) + \frac{1}{3}t - 2\delta \geq \frac{1}{4}(r + 1) + \frac{1}{8}t - 2\delta = \frac{1}{4}(r + 1 + \frac{1}{2}t) - 2\delta > 2$$

if $\delta$ is small enough, by our assumption (ii). Hence by Lemma 3.1, there is a box $B$ in $(K_R)^{m_1+t}$ such that if $E(\alpha)$ denotes the exponential sum attached to $C(X, Y)$, the contribution of the major arcs to the integral of $E(\alpha)$ is

$$AP^{(m_1+t-3)n} + o(P^{(m_1+t-3)n}) \quad (A > 0).$$

We shall now show that the contribution of the ‘minor arcs’ $m$ is $o(P^{(m_1+t-3)n})$. Let $B^{(1)}$ denote the projection of the box $B$ in $(K_R)^{m_1+t}$ onto the product of the first $m_1$ components and $B_t$ the projection into the
let $C^{(1)}(X)$ denote the exponential sum associated to $C^{(1)}$ and the box $B^{(1)}$, and $T_{d_i}(\alpha)$ the exponential sum associated to $d_iY_i^3$ and the box $B_i$, for $i = 1, \ldots, t$. We then have

$$E(\alpha) = E^{(1)}(\alpha) \prod_{i=1}^{t} T_{d_i}(\alpha).$$

The conditions of Lemma 2.2 are fulfilled by the form $C^{(1)}(X)$ with $\kappa = \frac{1}{2}(r + 1)\theta(1 - \delta)$, and we obtain the estimate

$$|E^{(1)}(\alpha)| < P(m_1 - \frac{1}{2}(r + 1)\theta(1 - \delta))n$$

for $P$ large and $\alpha \in m_\theta$. Hence by Lemma 4.1, we get for $\alpha \in m_\theta$

$$|E(\alpha)| < P(m_1 - \frac{1}{2}(r + 1)\theta(1 - \delta) + t - \frac{1}{4}t^2)\theta(n).$$

Applying this with $\theta = \frac{7}{8}$, we get

$$\int_{m_\theta}^{m_\theta} |E(\alpha)| d\alpha = o(P(m_1 + t - 3)n),$$

since

$$m_1 - \frac{1}{2}(r + 1)\frac{7}{8}(1 - \delta) + t - \frac{7t}{32} < m_1 + t - \frac{1}{2}(8 - \frac{1}{2}t)\frac{7}{8}(1 - \delta) - \frac{7t}{32} = m_1 + t - \frac{1}{2} + \frac{7\delta}{32}(16 - t) < m_1 + t - 3$$

if $\delta$ is small.

Now let $\theta_0 > \theta_1 > \theta_2 > \ldots > 0$ be a decreasing sequence of positive real numbers, to be chosen suitably later. We shall estimate the integral of $E(\alpha)$ on the set $m_{\theta_{g+1}} - m_{\theta_g}$. Since $m_{\theta_{g+1}} - m_{\theta_g} \subseteq \mathcal{E}(\theta_g)$, we obtain by the above estimate for $E(\alpha)$,

$$\int_{m_{\theta_{g+1}} - m_{\theta_g}} |E(\alpha)| d\alpha \ll |\mathcal{E}(\theta_g)| P^{U_n} \ll P^{V_n},$$
where
\[ U = m_1 - \frac{1}{2}(r + 1)\theta_{g+1}(1 - \delta) + t - \frac{1}{4}t\theta_{g+1}, \]
and
\[ V = m_1 + t - 3 + 4\theta_g + 2\delta - \frac{1}{2}(r + 1)\theta_{g+1}(1 - \delta) - \frac{1}{4}t\theta_{g+1}. \]
Hence
\[ \int_{m_{\theta_{g+1}} - m_{\theta_g}} |E(\alpha)|d\alpha = o(P^{(m_1 + t - 3)n}) \]
if \[ 4\theta_g - \frac{1}{2}(r + 1)\theta_{g+1} - \frac{1}{4}t\theta_{g+1} + \delta(2 + \frac{7}{16}(r + 1)) < \theta \]
i.e. \[ 4(\theta_g - \theta_{g+1}) + \theta_{g+1}\left\{4 - \frac{1}{2}(r + 1) - \frac{1}{4}t\right\} < -\left\{2 + \frac{7}{16}(r + 1)\right\}\delta. \]
This inequality clearly holds if \( \theta_{g+1} \) remains greater than a fixed positive quantity (independent of \( \delta \)), \( \delta \) is small enough and the jumps \( \theta_g - \theta_{g+1} \) are less than a positive quantity. Hence we can find a finite sequence
\[ \frac{7}{8} = \theta_0 > \theta_1 > \ldots > \theta_G \text{ with } \frac{1}{4n} < \theta_G < \frac{1 - \delta(n + 2)}{2n}, \]
such that
\[ \int_{m_{\theta_{g+1}} - m_{\theta_g}} |E(\alpha)|d\alpha = o(P^{(m_1 + t - 3)n}). \]
Since \( m_{\theta_G} = m \), we finally reach the conclusion that the number \( \mathcal{N}(P) \) of integral points \((X, Y)\) in \( P \mathcal{B} \) for which \( C(X, Y) = 0 \) satisfies
\[ \mathcal{N}(P) = \int_{\mathcal{B}} E(\alpha)d\alpha = AP^{(m_1 + t - 3)n} + o(P^{(m_1 + t - 3)n}) \quad (A > 0). \]
Since this is positive for \( P \) large, it follows that \( C(x, Y) \) represents zero non-trivially, which is a contradiction, proving Lemma 4.3.

We have tabulated below for \( 0 \leq t \leq 8 \) the associated values of \( r \) and the minimum permissible value of \( m_1 \) for the validity of Lemma 4.3.
The main theorem stated at the beginning of this paper can be easily deduced from the above lemma.

Let \( C(X) \) be a form with symmetric integral coefficients in \( K \) in at least 54 variables. If it does not represent zero, the above lemma says that it must represent a form of the type \( C_1(X') + d_1Y_1^3 \), where \( C_1 \) is a form in at least 46 variables. The form \( C_1(X') + d_1Y_1^3 \) cannot represent zero either, and another application of the lemma shows that \( C_1 \) represents a form of the type \( C_2(X'') + d_2Y_2^3 \), where \( C_2 \) is a form in at least 39 variables. Hence \( C(X) \) represents the form \( C_2(X'') + d_1Y_1^3 + d_2Y_2^3 \). Continuing in this way, we get finally that \( C(X) \) represents a form of the type

\[
C_8(Z) + d_1Y_1^3 + \ldots + d_8Y_8^3,
\]

which therefore cannot represent zero non-trivially. Let \( d_0 \) be any value taken by \( C_8(Z) \) with \( Z \neq (0) \); then \( C(X) \) represents \( d_0Y_0^3 + d_1Y_1^3 + \ldots + d_8Y_8^3 \) and hence this form cannot have a non-trivial zero. But by a theorem of Birch ((1), p.458), we know that any diagonal cubic form in at least 9 variables represents zero non-trivially. Hence there exist \( Y_0^0, \ldots, Y_8^0 \), not all zero, such that \( Y_i = Y_i^0 \) is a zero of the form written above. This is a contradiction.

The theorem is therefore proved. \( \square \)

The author wishes to thank Prof. K. G. Ramanathan for suggesting the problem to him and for being of great help in the preparation of this
paper, and Prof. K. Chandrasekharan for constant advice and encouragement.

Sums of \(m\)-th Powers in \(p\)-Adic Rings

By C.P. Ramanujam

0 Introduction and notations

Let \(A\) be a complete discrete valuation ring of characteristic zero with finite residue field, and for any integer \(m > 1\), let \(J_m(A)\) be the subring of \(A\) generated by the \(m\)-th powers of elements of \(A\). We will prove that any element of \(J_m(A)\) is a sum of at most \(8m^5\) \(m\)-th powers of elements of \(A\). We will also prove a similar assertion when the residue field of \(A\) is only assumed to be perfect and of positive characteristic, with the number \(\Gamma(m)\) of summands depending only on \(m\) and not on \(A\).

It follows from this and Theorem 2 of Birch [1] (see also Körner [2]) that any totally positive integer of sufficiently large norm in any algebraic number field belonging to the order generated by the \(m\)-th powers of integers of this field is actually a sum of at most \(\max(2^m + 1, 8m^5)\) \(m\)-th powers of totally positive integers of this field. This answers a question raised by Siegel [3] in the affirmative.

The author has been informed that Dr. B. J. Birch has also solved substantially the same problem by a different method, and that Dr. Birch’s work will be published in the Mordell issue of Acta Arithmetica.

Notations. \(A\) will denote a complete discrete valuation ring, \(p\) its maximal ideal, and \(\pi\) a generator of \(p\). The residue field \(k = A/p\) is assumed to be perfect of characteristic \(p > 0\), and \(q = p^f\) will denote the number of elements in \(k\) when this is finite. Let \(e\) be the ramification index of \(A\), and \(B\) the maximal unramified complete discrete valuation ring contained in \(A\) with the same residue field \(k\).

For any integer \(m > 1\), we write \(m = n \cdot p^r\), with \(r \geq 0\) and \((n, p) = 1\). \(J_m(A) = J_m\) will denote the subring of \(A\) generated by the \(m\)-th powers of elements of \(A\). When \(k\) is finite, we denote by \(f_1\) the least positive
divisor of \( f \) such that \( \frac{p^f - 1}{p^h - 1} \) divides \( n \), and we write \( q_1 = p^h \). We put \( \tau = r + 1 \) or \( r + 2 \) according as \( p \) is greater than or equal to 2.

\( \gamma_1(m), \gamma_2(m), \Gamma(m) \) denote positive integers depending only on \( m \) and not on \( A \) or \( p \).

1 The unramified case.

We start with a known lemma (Lemma 5 of Birch [1] or Theorem 7 of Stemmler [4]), whose proof we reproduce for completeness.

**Lemma 1.** When \( k \) is infinite, \( J_n = A \) and any element of \( A \) is the sum of at most \( \gamma_1(n) \) \( n \)-th powers.

When \( k \) is finite, let \( k_1 \) be its subfield with \( q_1 \) elements. Then \( J_n \) is the inverse image of \( k_1 \) under the natural homomorphism of \( A \) onto \( k \), and any element of \( J_n \) is the sum of at most \((n + 1)\) \( n \)-th powers.

[Mathematika 10 (1963), 137-146]

**Proof.** When \( k \) is finite, \( k_1 \) is evidently the set of elements of \( k \) which are sums of \( n \)-th powers of elements of \( k \). By Theorem 1 of Tornheim [5], any element of \( k_1 \) is the sum of \( n \) \( n \)-th powers. Hence any unit \( \alpha \) of \( A \) whose image in \( k \) lies in \( k_1 \) can be written as

\[
\alpha \equiv \sum_{i=1}^{n} x_i^n \pmod{p}, \quad x_i \in A.
\]

Since at least one \( x_i \) is a unit and \((n, p) = 1\), it follows from Hensel’s lemma that \( \alpha \) is a sum of \( n \) \( n \)-th powers. If \( \alpha \) were a non-unit, we write \( \alpha = (\alpha - 1) + 1^n \), and the assertion follows.

If \( k \) is infinite, it follows from Theorem 2 and the proofs of Theorem 4 and its Corollary 1 of Tornheim [5] that any element of \( k \) is a sum of \( \gamma'_1(n) \) \( n \)-th powers of \( k \), and our assertion follows as before.

The next lemma says that a congruence modulo a high power of \( p \) can be refined to an equality, and is again well known (see Theorem 12 of Stemmler [4]).
Lemma 2. If
\[ \sum_{i=1}^{a} x_i^m \equiv y \mod p^r A \]
and \( x_1 \) is a unit, there is an \( x'_1 \in A \), \( x'_1 \equiv x_1 \mod pA \) with \( y = (x'_1)^m + \sum_{2}^{a} x_i^m \).

Proof. Suppose we have found a \( z \in A \) with \( z \equiv x_1 \mod pA \) satisfying
\[ z^m \equiv y - \sum_{2}^{a} x_i^m \mod p^s A \]
for some \( s \geq r \). If we put \( z_1 = z + \lambda p^{s-r} \), it follows easily that
\[ z_1^m \equiv z^m + z^{m-1} \cdot n \lambda p^{s} \mod p^{s+1} A, \]
and since \( nz^{m-1} \) is a unit, we can find \( \lambda \in A \) such that
\[ z_1^m \equiv y - \sum_{2}^{a} x_i^m \mod p^{s+1} A. \]
Since \( A \) is complete, the lemma follows. \( \square \)

Lemma 3. Let \( C \) be a commutative ring, \( a \) an ideal of \( C \), and \( s \) an integer \( \geq 0 \). We denote by \( a^{(p^s)} \) the set of \( p^s \)-th powers of elements of \( a \), and by \( a_s \) the set of elements of \( C \) of the form \( a_0 + pa_1 + \ldots + p^sa_s \) with \( a_i \in a^{(p^{s-i})} \). Then \( C_s \) is a subring of \( C \), and \( a_s \) an ideal of \( C_s \). If \( x, y \in C \), with \( x \equiv y \mod a \), then \( x^{p^s} \equiv y^{p^s} \mod a_s \).

Proof. This being trivial for \( s = 0 \), we may assume that \( s \geq 1 \), and that the lemma holds with \( s - 1 \) instead of \( s \). Since \( C_s = C^{(p^s)} + pC_{s-1} \), the inclusions \( C_s \cdot C_s \subseteq C_s \) and \( pC_{s-1} + pC_{s-1} \subseteq pC_{s-1} \) are trivial, and only the inclusion \( C^{(p^s)} + C^{(p^s)} \subseteq C_s \) remains to be verified. For \( x, y \in C \), we have
\[ x^{p^s} + y^{p^s} = (x + y)^{p^s} - \sum_{0<i<p^s} \left( \begin{array}{c} p^s \\ i \end{array} \right) x^i y^{p^s-i}, \]
for \( x, y \in C \).
and if $p^k || i$, $p^{s-k} | {p^r \choose i}$, and hence by induction hypothesis, $- \sum \in \in pC_{s-1}$, and the right side belongs to $C_s$. Thus $C_s$ is a ring, and $a_s$ a subring of $C_s$, and clearly $C_s a_s \subset a_s$. Finally, if $z = x + y$ with $y \in a$, it follows from (1) that $x^{p^r} \equiv (x+y)^{p^r} \equiv z^{p^r} (\text{mod } a_s)$, which completes the proof of the lemma. □

It follows that the set $J'_m = \{ x_0^{p^r} + px_1^{p^{r-1}} + \ldots + px_r x_i | x_i \in J_n \}$ is a subring of $A$, and we have evidently the inclusion $J'_m \subset J_m$.

**Proposition 1.** Assume that $r \geq 1$ and that $A$ is unramified. If $k$ is infinite, $J_m = J'_m = A$ and any element of $A$ is a sum of at most $\gamma_2(m)$ $m$-th powers.

If $k$ is finite, any element of $J_m$ is a sum of at most $p^{r-1} = \frac{1}{p-1} n + \delta m$-th powers, where $\delta = 1$ if $n = p - 1$ and $\delta = 0$ otherwise. Moreover, $J_m = J'_m$ unless $p = 2$ and $f_1 \neq f$.

**Proof.** First consider the case when $k$ is finite and $p > 2$. We put $m_s = n \cdot p^s (0 \leq s \leq r)$, and we shall show (with the notation of Lemma 3) any element of $(J_n)_s$ is the sum of at most $\frac{p^{s+1} - 1}{p - 1} n m_s$-th powers modulo $p^{s+1} A$. For $s = 0$, this is the theorem of Tornheim quoted earlier. Suppose the result is true for $s$, and let $x = x_0^{p^{s+1}} + y \in (J_n)_s$, with $y \in p(J_n)_s$. By the theorem of Tornheim, there exist $y_1, \ldots, y_n \in A$ such that $x_0 \equiv \sum y_i^n (\text{mod } pA)$, hence

$$x_0^{p^{s+1}} \equiv \left( \sum y_i^n \right)^{p^{s+1}} (\text{mod } p^{s+2} A) \quad \text{and} \quad \left( \sum y_i^n \right)^{p^{s+1}} \equiv \sum y_i^{m_{s+1}} (\text{mod } p(J_n)_s),$$

as follows from (1) with $s + 1$ instead of $s$. Thus we obtain by induction hypothesis,

$$x \equiv \sum y_i^{m_{s+1}} + p \sum z_j^m, \quad (\text{mod } p^{s+2} A),$$
where \( N = \frac{p^{s+1} - 1}{p - 1} \cdot n \). Since the residue field is perfect, we can find \( t_j \) such that \( t_j^p \equiv z_j (\text{mod } pA) \), and hence \( t_j^{m_{s+1}} \equiv z_j^{m_{s+1}} (\text{mod } p^{s+1}A) \), which gives

\[
x \equiv \sum_{i=1}^{n} y_i^{m_{s+1}} + p \sum_{i=1}^{N} t_i^{m_{s+1}} \pmod{p^{s+2}A},
\]

i.e., \( x \) is a sum of \( n + pN = n \cdot \frac{p^{s+2} - 1}{p - 1} \) \( m_{s+1} \)-th powers modulo \( p^{s+2}A \).

This completes the induction, and we obtain for \( s = r \) that any \( x \in J'_m \) is the sum of at most \( \frac{p^r - 1}{p - 1} \cdot n \) \( m \)-th powers modulo \( p^{r+1}A \), and it is easily deduced from Lemma 2 that \( x \) is actually the sum of this many \( m \)-th powers if \( x \not\equiv 0 (p^r) \). Further, if \( n < p - 1 \) and \( \zeta \) is a primitive \((p - 1)\)-th root of unity in \( A \), \( \sum_{i=0}^{p-2} \zeta^{mi} = 0 \), and if \( n \geq p - 1, 0 \equiv 1 + \ldots + 1 (\text{mod } p^r) \).

This proves the assertion when \( x \equiv 0 (p^r) \), in view of Lemma 2.

Next consider the case when \( J_n = A \), and suppose that every element of \( A \) is a sum of \( \lambda \) \( n \)-th powers modulo \( pA \). Since the residue field is perfect, it follows that sums of \( \lambda m \)-th powers form a system of representatives for the residue classes mod \( pA \). Since any element \( x \in A \) can be represented as \( x = x_0 + x_1p + \ldots + x_{r-1}p^{r-1} (\text{mod } p^rA) \) with \( x_i \) chosen from this system of representatives, it follows from Lemma 2 that any element of \( A \) which is \( \not\equiv 0 (\text{mod } p^r) \) is a sum of

\[
(1 + p + \ldots + p^{r-1})\lambda = \frac{p^r - 1}{p - 1} \cdot \lambda
\]

\( m \)-th powers. Elements \( x \equiv 0 (p^r) \) can be dealt with as before. This settles the case of the infinite residue field as well as the case of \( p = 2 \) and \( J_n = A \).

If \( p = 2 \) and \( J_n \neq A \), it follows from Lemma 1 that \( f_1 \neq f \) and hence \( f_1 \leq f/2, n \geq \frac{2f - 1}{2f_1 - 1} \geq 2^{f/2} + 1, \) and \( 2f \leq (n - 1)^2 \). We give an argument whose idea goes back to Siegel [3].

Let \( \bar{x}_1^m, \ldots, \bar{x}_d^m \) be a minimal set of generators (as an additive group) of the image of \( J_m(A) \) in \( A/2^{r+2}A \), and \( q_i \) the index of the subgroup generated by \( \{ \bar{x}_1^m, \ldots, \bar{x}_{i-1}^m \} \) in the subgroup generated by \( \{ \bar{x}_1^m, \ldots, \bar{x}_i^m \} \). Then
$q_i \leq 2^{r+2}$, each $q_i$ is a positive power of 2 and $q_1 \ldots q_d \leq 2^{(r+2)f}$. Any element of $J_m(A)$ can therefore be written as a sum of at most $\sum_{i=1}^{d} (q_i - 1)$ $m$-th powers modulo $2^{r+2}A$. We shall find an upper bound for

$$\sum_{i=1}^{d} (q_i - 1) = \sum_{i=1}^{d} \min(q_i - 1, 2^{r+2} - 1).$$

Let $N$ be the supremum of all sums $S = \sum_{i=1}^{l} \min(n_i - 1, 2^{r+2} - 1)$, where $l$, $n_1, \ldots, n_l$ vary subject to the following conditions: each $n_i (1 \leq i \leq l)$ is a positive power of 2 and $n_1 \ldots n_l \leq 2^{(r+2)f}$. Suppose $l = d'$, $n_i = q'_i (1 \leq i \leq d')$ is a choice of the variables for which $S$ attains its supremum, with $l$ minimal. We assert that for all but one $i$, $q'_i \geq 2^{r+2}$. If not, suppose for instance that $q'_{d'-1} < 2^{r+2}$, $q'_{d'} < 2^{r+2}$. Since all the $q'_i$ are powers of 2, it follows that $q'_{d'-1} + q'_{d'} \leq 2^{r+2}$. If we define $q''_i = q'_i$ for $1 \leq i \leq d' - 2$, $q''_{d'-1} = q'_{d'-1} \cdot q'_{d'}$, we have

$$\min(q'_{d'-1} - 1, 2^{r+2} - 1) + \min(q'_{d'} - 1, 2^{r+2} - 1)$$

$$= (q'_{d'-1} - 1) + (q'_{d'} - 1) \leq \min(q''_{d'-1} - 1, 2^{r+2} - 1),$$

$$N = \sum_{i=1}^{d'} \min(q'_i - 1, 2^{r+2} - 1) \leq \sum_{i=1}^{d'-1} \min(q'_i - 1, 2^{r+2} - 1) \leq N,$$

since $q'_1 \ldots q'_{d'-1} = q''_1 \ldots q'_{d'} \leq 2^{(r+2)f}$, which contradicts the minimality of $d'$. Hence for all but one $i$, $q'_i \geq 2^{r+2}$, and all the $q'_i$ are $\geq 2$, and therefore

$$2^{(r+2)(d'-1) + 1} \leq q'_1 \ldots q'_{d'} \leq 2^{(r+2)f}, d' \leq f.$$ 

It follows that

$$N = \sum_{i=1}^{d'} \min(q'_i - 1, 2^{r+2} - 1) \leq f(2^{r+2} - 1) \leq \frac{2 \log(n - 1)}{\log 2} (2^{r+2} - 1) < n(2^{r+2} - 1).$$

It follows from Lemma that any element of $J_m(A)$ is a sum of at most $(2^{r+2} - 1)n$ $m$-th powers. This completes the proof of Proposition □
2 The case when the residue field is large

**Proposition 2.** When \( k \) is infinite, \( J_m = J'_m = A \), and any element of \( A \) is a sum of at most \( \gamma_3(m) \) \( m \)-th powers.

When \( k \) is finite, and \( f_1 > r \geq 1 \), any element of \( J_m \) is a sum of at most \( \{ (r+1)(p^r+1)+1 \} \left\{ \frac{p^r-1}{p-1}n + \delta \right\} \) \( m \)-th powers, where \( \delta = 1 \) if \( n = p-1 \) and \( \delta = 0 \) otherwise; and the equality \( J_m = J'_m \) holds unless \( p = 2 \) and \( f \neq f_1 \).

**Proof.** When either \( k \) is infinite or \( f_1 > r \), we can find elements \( u_0, \ldots, u_{p^r} \in J_m(B) \) such that their residue field images are distinct, by Lemma 1. It follows that we can find \( a_0, \ldots, a_{p^r} \in J_m(B) \) such that

\[
p^l x^{p^r-1} = \sum_{i=0}^{p^r} a_i (u_i x + 1)^{p^r}.
\]

In fact, writing

\[
\binom{p^r}{p^{r-1}} = p^l \alpha_l,
\]

where \( \alpha_l \) is a unit in \( J_m(B) \), we have only to solve the system of linear equations

\[
\sum_{i=0}^{p^r} a_i u_i^v = \begin{cases} 
0 & \text{if } v \neq p^{r-1}, \quad 0 \leq v \leq p^r \\
\alpha_l^{-1} & \text{if } v = p^{r-1}
\end{cases}
\]

for the \( a_i \) in \( J_m(B) \). The determinant \( \Delta = \prod_{i<j}(u_i - u_j) \) is an element of \( J_m(B) \) invertible in \( B \), hence in \( J_m(B) \), since \( \Delta(\Delta^{m-1}(\Delta^{-1})^m) = 1, \Delta^{m-1}(\Delta^{-1})^m \in J_m(B) \). Thus the \( a_i \) can be solved for in \( J_m(B) \).

Now for \( x \in p, (1+u_i x)^{p^r} \) is an \( m \)-th power by Hensel’s lemma. It follows that if any element of \( J_m(B) \) is a sum of \( \lambda \) \( m \)-th powers, any element of \( m_r \) (in the notation of Lemma 3) is the sum of at most \( \lambda(r+1)(p^r+1) \) \( m \)-th powers. But since any element of \( A \) is congruent to an element of \( B \) modulo \( p \), it follows from Lemma 3 that any element of \( J_m(A) \) or \( J'_m(A) \) is congruent to an element of \( J_m(B) \) or \( J'_m(B) \) respectively modulo \( p_r \).

Proposition 2 follows from this, if we substitute for \( \lambda \) from Proposition 1. \( \square \)

**Remarks.** (1) It follows from the proof that the Proposition is true for any complete local ring with residue field finite and \( f_1 > r \), or
perfect and infinite of characteristic \( p > 0 \), since such a ring contains a homomorphic image of an unramified complete discrete valuation ring of characteristic zero with the same residue field, by the structure theorems of Cohen.

(2) When \( n = 1 \), that is when \( m = p^r \), the passage from \( J_m(A) \) to \( J_m(B) \) [or from \( J'_m(A) \) to \( J'_m(B) \)] is not necessary, and we can apply (2) to any element \( x \in A \) directly. Thus if every element of \( J_m(B) \) is a sum of at most \( \lambda m \)-th powers, every element of \( J_m(A) \) is a sum of at most \( (r + 1)(p^r + 1)\lambda m \)-th powers.

Moreover when \( n = 1 \), the case \( f = r \) can also be dealt with in the same manner. In fact if \( \zeta \) is a primitive \( (p^f - 1) \)-th root of unity in \( B \), we have the identities

\[
(p^f - 1) \left( \frac{p^r}{p^k} \right)^{x^{p^k}} = \sum_{i=0}^{p^f - 2} \zeta^{-ip^k}(\zeta^i x + 1)^{p^r}, \quad 0 < k < r,
\]

\[
(p^f - 1)(p^r x + x^{p^r}) = \sum_{i=0}^{p^f - 2} \zeta^{-i}(\zeta^i x + 1)^{p^r},
\]

and \( \zeta \) is a \( p^r \)-th power in \( B \).

(3) Since \( p^{f_1} - 1 \geq \frac{p^f - 1}{n} \), the condition \( f_1 > r \) is certainly fulfilled if \( p^f > m \). Since the case \( p^f = m \) is also covered by Remark (2), we may assume in what follows that \( p^f < m \).

### 3 The general case

We assume \( A \) to have finite residue field, and that \( f_1 \leq r, p^f < m \). The method is similar to that of \( \S 2 \) but more complicated.

Let \( \zeta \) be a primitive \( (q_1 - 1) \)-th root of unity in \( B \). It is easily seen that \( \zeta \in J_m(B) \). For any \( k \) with \( 0 \leq k \leq r \), we wish to establish an identity of the form

\[
\sum_{j}^{q_1 - 2} \sum_{i=0}^{a_{ij}} (\zeta^i \lambda_j x + 1)^{p^r} = p^{r-k}(\lambda x)^{p^k}
\]
with \( a_{ij} \), \( \lambda_j \) and \( \lambda \) suitably chosen. This identity is equivalent to the system of linear equations

\[
\sum_{i,j} a_{ij} \zeta^{ij} \lambda_j^v = \begin{cases} 0 & \text{if } v \neq p^k, \quad 0 \leq v \leq p^r, \\ p^{r-k} \lambda^p & \text{if } v = p^k. \end{cases}
\]

If we put \( \sum a_{ij} \zeta^{ij} = b_{jv} \), then \( b_{jv} = b_{jv'} \) if \( v \equiv v' \pmod{(q_1 - 1)} \). We naturally choose \( b_{jv} = 0 \) if \( v \neq p^k \pmod{(q_1 - 1)} \), and we will choose \( b_{jv} = c_j \) for \( v \equiv p^k \pmod{(q_1 - 1)} \) later. The \( a_{ij} \) are then determined by the \( c_j \) by the equations \( a_{ij} = u_i \cdot c_j \) with \( u_i \in J_m(B) \). Let us write \( p^k = \sigma(q_1 - 1) + \rho_1, p^r - \rho_1 = \kappa(q_1 - 1) + \rho_2 \), with \( 0 \leq \rho_1, \rho_2 < q_1 - 1 \); if \( q_1 > 2 \) and \( l \) and \( s \) are the least non-negative residues of \( k \) and \( r \) modulo \( f_1 \), it is easily checked that

\[
\sigma = \frac{p^k - p^l}{q_1 - 1}, \quad \rho_1 = p^l, \quad \text{and} \quad \kappa = \frac{p^r - p^s}{q_1 - 1} \quad \text{or} \quad \frac{p^r - p^s}{q_1 - 1} - 1
\]

according as \( s \geq 1 \) or \( s < l \). We let the index \( j \) vary through the range \( 0 \leq j \leq \kappa \). We write \( \left( \frac{p^r}{p^k} \right) = p^{r-k} m_k \), where \( m_k \) is a unit in \( J_m(B) \). Putting

\[
\lambda_j^{q_1 - 1} = \mu_j, \quad m_k c_j \lambda_j^{\rho_1} = d_j, \quad \text{so that} \quad a_{ij} = m_k^{-1} \lambda_j^{\rho_1} u_i d_j, \quad \text{the equation } \lambda_j \text{ becomes equivalent to the system of linear equations.}
\]

\[
\sum_{j=0}^{\kappa} d_j \mu_j = \begin{cases} 0 & \text{if } t \neq \sigma, \quad 0 \leq t \leq \kappa \\ \lambda^{p^\sigma} & \text{if } t = \sigma. \end{cases}
\]

We choose \( \lambda_j = \pi^{jm}(0 \leq j \leq \kappa) \), so that \( \mu_j = \pi^{jm(q_1 - 1)} \). If \( S_{\alpha}(X_0, \ldots, X_\beta) \) denotes the elementary symmetric function of degree \( \alpha \) in the variables \( X_0, \ldots, X_\beta \), the solution of the above system of linear equations for the \( d_j \) is

\[
d_j = \pm \lambda^{p^k} S_{\kappa-\sigma}(\mu_0, \ldots, \hat{\mu}_j, \ldots, \mu_\kappa) / \prod_{\alpha \neq j} (\pi^{jm(q_1 - 1)} - \pi^{am(q_1 - 1)})
\]

and hence

\[
a_{ij} = \pm \frac{m_k^{-1} u_i \lambda^{p^k} S_{\kappa-\sigma}(\mu_0, \ldots, \hat{\mu}_j, \ldots, \mu_\kappa)}{\pi^{imp_1} \prod_{\alpha \neq j} (\pi^{jm(q_1 - 1)} - \pi^{am(q_1 - 1)})}
\]
where the symbol ‘^’ over a letter means that it is to be omitted. Now

\[ S_{\kappa-\sigma}(\mu_0, \ldots, \hat{\mu}_j, \ldots, \mu_k) = \pi^{m(q_1-1)(\kappa-\sigma-1)(\kappa-\sigma)/2} P_j(\pi^{m(q_1-1)}) \]

where \( P_j \) is a polynomial of degree \( \leq (\sigma + 1)(\kappa-\sigma) \) with rational integral coefficients. The above expression for the \( a_{ij} \) may be rewritten as

\[ a_{ij} = \pm \frac{m_k^{-1} u_i \lambda_{ij} \pi^{\frac{1}{2}[(\kappa-\sigma-1)(\kappa-\sigma)] - \frac{j}{2}(j-1)m(q_1-1) - j\rho_1}}{\prod_{\alpha=1}^{\kappa} (1 - \pi^{m\alpha(q_1-1)}) \prod_{\alpha=1}^{\kappa} (1 - \pi^{m\alpha(q_1-1)})} \]

We wish to choose \( \lambda \) in such a way that it is divisible by as small a power of \( p \) as possible, and such that the \( a_{ij} \) are sums of as few a number of \( m \)-th powers as possible.

Let \( p^X \) be the power of \( p \) dividing \( \lambda \). In order that the \( a_{ij} \) belong to \( A \) at all, we must have

\[ p^k X + \left( (\kappa - \sigma - 1)(\kappa - \sigma) - \frac{(j-1)j}{2} - (\kappa - j)j \right) m(q_1-1) - j\rho_1 \geq 0 \]

\((0 \leq j \leq \kappa)\).

The minimum of the left side of the above inequality as \( j \) varies in the range \( 0 \leq j \leq \kappa \) is attained for \( j = \kappa \), so that we must have [on substituting \( p^k = \sigma(q_1 - 1)\rho_1 \)]

\[ p^k (X - \kappa m) + m(q_1 - 1) \frac{\sigma(\sigma + 1)}{2} \geq 0. \]

We choose \( X \) in such a way that equality holds. We put

\[ \lambda = \pi^X \prod_{j=1}^{\kappa} (1 - \pi^{im(q_1-1)}). \]

It is easily checked that the polynomial \( \prod_{j=1}^{\alpha} (1 - Y^j) \prod_{j=1}^{\kappa-\alpha} (1 - Y^j) \) divides \( \prod_{j=1}^{\kappa} (1 - Y^j) \), so that we obtain

\[ a_{ij} = \pi^{um} Q_j(\pi^{m(q_1-1)}), \quad u = u(j) \geq 0 \]
where $Q_j$ is a polynomial with coefficients in $J_m(B)$ of degree

$$\leq (\sigma + 1)(\kappa - \sigma) + p^k \frac{\kappa(\kappa + 1)}{2} - \frac{j(j + 1)}{2} - \frac{(\kappa - j)(\kappa - j + 1)}{2}$$

$$= (\sigma + 1)(\kappa - \sigma) + (p^k - 1) \frac{\kappa(\kappa + 1)}{2} + j(\kappa - j).$$

It follows from (3) that for any $x \in p^{X+1}$, $p^{r-k}x^p$ is a sum of at most

$$N(q_1 - 1) \left( (\kappa + 1) \left\{ (\sigma + 1)(\kappa - \sigma) + (p^k - 1) \frac{\kappa(\kappa + 1)}{2} \right\} + \sum_{j=0}^{\kappa} j(\kappa - j) \right)$$

$m$-th powers, where $N$ denotes the smallest integer such that any element of $J_m(B)$ is the sum of at most $N$ $m$-th powers. Let us put $\kappa_0 = \left\lfloor \frac{p^r}{q_1 - 1} \right\rfloor$, so that $\kappa \leq \kappa_0$ for all $k$; the above integer is then $\leq N(q_1 - 1)p^k\kappa_0(\kappa_0 + 1)^2/2$.

Hence if we put $Y = 1 + \sup_{0 \leq k \leq r} X$ and $a = p^Y$, any element of $a_r$ (in the notation of Lemma 3) is the sum of at most $m$-th powers. Since

$$X = km + p^{r-k}n(q_1 - 1)\frac{\sigma(\sigma + 1)}{2} = km + n\frac{(\sigma + 1)}{2}(p^r - \rho_1 p^{r-k}),$$

and $\sigma$ and $(p^r - \rho_1 p^{r-k})$ are both non-decreasing as $k$ increases, we see that

$$\sup_{0 \leq k \leq r} X = \kappa_0 m + n(q_1 - 1)\frac{\kappa_0(\kappa_0 + 1)}{2}.$$

Now, if $\bar{J}$ denotes the image of $J_m(A)$ in the ring $A_r/a_r + p^rA$, the order (as an abelian group) of $\bar{J}$ is of the form $p^Q$ where

$$Q \leq (r + 1)f \left( \kappa_0 m + n(q_1 - 1)\frac{\kappa_0(\kappa_0 + 1)}{2} + 1 \right),$$
by Lemma 3. Choose a minimal set $\bar{x}_1^m, \ldots, \bar{x}_d^m$ of generators of $\bar{J}$ (as an abelian group), and denote by $q_i$ the index of the subgroup $\{\bar{x}_i^m, \ldots, \bar{x}_{i-1}^m\}$ in the subgroup $\{\bar{x}_i^m, \ldots, \bar{x}_1^m\}$ for $1 \leq i \leq d$, so that $p^r \geq q_i > 1$, each $q_i$ is a power of $p$ and $q_1 \ldots q_d = p^Q$. Any element of $\bar{J}$ is then a sum of at most $\sum_1^d (q_i - 1)$ elements of the form $\bar{x}_i^m$. Arguing as in the last part of the proof of Proposition 2, we obtain that

$$\sum_{i=1}^d (q_i - 1) \leq \sum_{j=1}^{d'} \min(q'_j - 1, p^r - 1),$$

where each $q'_j$ is again a positive power of $p$, $\prod q'_j = p^Q$, and all but one of the $q'_j$ satisfy $q'_j \geq p^\tau$. Thus we obtain

$$p^{(d'-1)\tau+1} \leq p^Q,$$

$$d' - 1 < (r+1)f \left( \kappa_0 m + n(q_1 - 1) \frac{\kappa_0 (\kappa_0 + 1)}{2} + 1 \right) / \tau$$

$$\leq f \left( \kappa_0 m + n(q_1 - 1) \frac{\kappa_0 (\kappa_0 + 1)}{2} + 1 \right),$$

i.e.

$$d' \leq f \left( \kappa_0 m + n(q_1 - 1) \frac{\kappa_0 (\kappa_0 + 1)}{2} + 1 \right),$$

and hence

$$\sum_{i=1}^d (q_i - 1) \leq f(p^\tau - 1) \left( \kappa_0 m + n(q_1 - 1) \frac{\kappa_0 (\kappa_0 + 1)}{2} + 1 \right).$$

54 It follows that any element of $J_m(A)$ is a sum of at most

$$N \frac{(q_1 - 1)\kappa_0 (\kappa_0 + 1)^2}{2} \frac{p^{r+1} - 1}{p - 1} + f(p^\tau - 1) \left( \kappa_0 m + n(q_1 - 1) \frac{\kappa_0 (\kappa_0 + 1)}{2} + 1 \right)$$

$m$-th powers. Now if $f = f_1$, then $f \leq r$ by assumption, and if $f \neq f_1$, then $f_1 \leq f/2$, so that

$$n \geq \frac{p^f - 1}{p^{f_1} - 1} \geq p^{f/2} + 1, \quad f \leq \frac{2 \log (n - 1)}{\log p}.$$
Using this and the value for $N$ as given by Proposition 1, one easily deduces after a little calculation that the above integer is $< 8m^5$. In view of Propositions 1 and 2 we thus have

**Proposition 3.** Let $A$ be any complete discrete valuation ring of characteristic zero with finite residue field, and $m$ an integer $> 1$. Then any element of the subring $J_m(A)$ of $A$ generated by $m$-th powers of elements of $A$ is a sum of at most $8m^5 m$-th powers.

**Remark.** As is needless to remark, the bound $8m^5$ is quite rough, and it is possible to obtain better estimates for particular values of $m$. In view of the fact that the “global to local” reduction of the number field case to that of a $p$-adic field works when the number of variables is at least $2^m + 1$ (Birch [1] and Körner [2]), and since $8m^5 < 2^m + 1$ for $m \geq 27$, it might not be without interest to check that $2^m + 1$ variables suffice for $m \leq 26$. For most values of this range, this is a consequence of our estimates, but the author has not checked this for all $m \leq 26$.

The author wishes to thank Professor K. G. Ramanathan for suggesting the problem and for his kind help. He is also indebted to Professor K. Chandrasekharan for several improvements.

A Note on Automorphism Groups of Algebraic Varieties *

By C.P. Ramanujam in Bombay (India)

Matsusaka has proved [3] that the maximal connected group of automorphisms of a projective variety can be endowed with the structure of an algebraic group. Our aim in this note is to extend this result to arbitrary complete varieties. More generally, we shall show that a “connected” and “finite dimensional” group $G$ of automorphisms (see below for precise definitions) of any algebraic variety $X$ can be endowed with the structure of an algebraic group variety. The main line of argument is similar to the one used by Chevalley [2] and Seshadri [7] in the construction of the Picard variety, but somewhat simpler. We shall prove that the linear map of the Lie algebra of this algebraic group into the space of vector fields on $X$ which associates to any tangent vector at the identity element of $G$ the corresponding “infinitesimal motion” is an injection. It follows easily that $G$ satisfies the universal property for connected algebraic families of automorphisms of $X$ containing the identity, that is, that any algebraic family of automorphisms of an algebraic variety $X$ parametrised by a variety $T$ is induced by a morphism of $T$ into $G$. As an application, we shall prove that the maximal connected group of automorphisms of a (locally isotrivial) principal fibre space over a complete variety has a structure of a group variety. We have been informed by the referee that this result has also been obtained by H. Matsumura.

All varieties will be assumed to be irreducible, and defined over an algebraically closed field $K$.

*The author wishes to express his gratitude to Professors M. S. Narasimhan and C.S. Seshadri for many helpful suggestions and discussions.
We shall say that a family \( \{ \varphi_t \}_{t \in T} \) of automorphisms of a variety \( X \)
where the parametrising set \( T \) is also a variety, is an algebraic family if the
map \( T \times X \to X \) given by \( (t, x) \mapsto \varphi_t(x) \) is a morphism. It is clear
that if \( \lambda : S \to T \) is a morphism, the family \( \{ \varphi_{\lambda(s)} \}_{s \in S} \) is again algebraic,
and that if \( \{ \psi_s \}_{s \in S} \) is another algebraic family, \( \{ \psi_s \circ \varphi_t \}_{(s, t) \in S \times T} \) is also an
algebraic family. Let \( (\tilde{X}, p) \) be the normalisation of \( X \). For every \( t \in T \),
\( \varphi_t \) lifts to a unique automorphism \( \varphi_t \) of \( \tilde{X} \) such that \( p \circ \varphi_t = \varphi_t \circ p \).
We shall show that \( \{ \varphi_t \}_{t \in T} \) is an algebraic family of automorphisms of
\( \tilde{X} \). Let \( (\tilde{T}, q) \) be the normalisation of \( T \). Then \( (\tilde{T} \times \tilde{X}, q \times p) \) is the
normalisation of \( T \times X \), and the morphism \( T \times X \to X \) lifts to a unique
morphism \( \bar{\varphi} : \tilde{T} \times \tilde{X} \to \tilde{X} \) such that \( p \circ \bar{\varphi} = \varphi \circ (q \times p) \). It follows that for
any \( \tilde{t} \in \tilde{T} \), the morphism of \( \tilde{X} \) onto itself given by \( \tilde{x} \mapsto \bar{\varphi}(\tilde{t}, \tilde{x}) \) coincides
with \( \tilde{\varphi}_q(\tilde{t}) \). Let \( \Gamma_{\bar{\varphi}} \) be the graph of \( \bar{\varphi} \) in \( \tilde{T} \times \tilde{X} \times \tilde{X} \), and \( \Gamma_{\bar{\varphi}} \) its image in
\( T \times \tilde{X} \times \tilde{X} \) by \( q \times I_{\tilde{X}} \times I_{\tilde{X}} \) denoting the identity map of \( \tilde{X} \). \( \Gamma_{\bar{\varphi}} \) is then
the graph of the map \( T \times \tilde{X} \to \tilde{X} \) given by \((t, \tilde{x}) \mapsto \bar{\varphi}_t(\tilde{x}) \) and since \( q \) is
proper, \( \Gamma_{\bar{\varphi}} \) is closed. Since the projection of \( \Gamma_{\bar{\varphi}} \) onto the product \( \tilde{T} \times \tilde{X} \)
of the first two factors is an isomorphism and \( q \times I_{\tilde{X}} : \tilde{T} \times \tilde{X} \to T \times \tilde{X} \)
is proper, it follows that the projection of \( \Gamma_{\bar{\varphi}} \) onto \( T \times \tilde{X} \) is a morphism
which is proper and bijective.

Let \( p_1 \) and \( p_2 \) be the projections of \( \Gamma_{\bar{\varphi}} \) onto the second and third factors.
It is easily checked that if \( \tau \) is a tangent vector at a point \((t, \tilde{x}, \varphi_t(\tilde{x})) \)
to \( \Gamma_{\bar{\varphi}} \) whose image by the differential map of the projection onto \( T \) is
zero, and if \( dp_i \) and \( d\varphi_t \) are the differential maps of \( p_i \) and \( \varphi_t \), we have
differential maps \( d\varphi_t \). It follows that the differential map of the projection
of \( \Gamma_{\bar{\varphi}} \) onto \( T \times \tilde{X} \) is everywhere injective. It follows from [5, Appendix, Exposé 5, p. 5-28] that \( \Gamma_{\bar{\varphi}} \to T \times \tilde{X} \) is an isomorphism every-where, which shows that \( \bar{\varphi} \) is a morphism and \( \{ \varphi_t \}_{t \in T} \) is an algebraic
family.

A similar argument proves that the family \( \{ \varphi_t^{-1} \}_{t \in T} \) of inverses of
an algebraic family is again algebraic. Since the set of points of a
parametrising variety for which the corresponding elements of an
algebraic family become the identity automorphism is a closed set, it follows that if \( \{ \varphi_t \}_{t \in T} \) and \( \{ \psi_s \}_{s \in S} \) are two algebraic families, the set of
\((s, t) \in S \times T \) for which \( \varphi_t = \psi_s \) is closed.
We shall say that a group $G$ of automorphisms of a variety $X$ is a connected group of automorphisms if any automorphism belonging to $G$ is a member of an algebraic family which also contains the identity automorphism of $X$. We shall say that $G$ is finite dimensional if there exists an integer $N$ such that if $\{\varphi_t\}_{t \in T}$ is any algebraic family of automorphisms contained in $G$ (i.e. $\varphi_t \in G$ for every $t \in T$) and such that $\varphi_t \neq \varphi_{t'}$ if $t \neq t'$ (an injective family), we have $\dim T \leq N$. The smallest integer $N$ having this property is then called the dimension of $G$.

We need a final definition. Let $\{\varphi_t\}_{t \in T}$ be an algebraic family of automorphisms of $X$ and $\varphi : T \times X \to X$ the defining morphism. Let $\tau$ be a tangent vector to $T$ at a point $t_0$, and for any $x$, let $\tau_x$ be the tangent vector to $T \times X$ at $(t_0, x)$ which is the image of $\tau$ by the differential mapping of the morphism $\theta_x : T \to T \times X$ given by $\theta_x(t) = (t, x)$. We can then define a vector field $d\varphi(\tau)$ on $X$ whose value $d\varphi(\tau)_x$ at the point $x$ is given by $d\varphi(\tau)_x = d\varphi(\tau_{\varphi t_0 x} - 1_x)$. The vector field $d\varphi(\tau)$ is immediately verified to be regular (i.e., maps regular functions on open subsets of $X$ into regular functions). We shall say that the family $\{\varphi_t\}_{t \in T}$ is infinitesimally injective at a point $t_0 \in T$ if $d\varphi$ is an injection of the tangent space at $t_0$ into the vector space of regular vector fields on $X$.

We now state our result.

**Theorem.** Let $G$ be a connected finite dimensional group of automorphisms of an algebraic variety $X$. Then there exists a unique structure of an algebraic variety on $G$ which makes of it an algebraic group (of dimension $= \text{dimension of } G$) such that the following condition holds:

a. The automorphisms of $X$ belonging to $G$, when considered as a family of automorphisms of $X$ parametrised by the identity map of $G$ onto $G$, is an algebraic family which is infinitesimally injective on $G$. In other words, if $\chi : G \times X \to X$ is defined by $\chi(\varphi, x) = \varphi(x)$, $\chi$ is a morphism of algebraic varieties, and if $\tau \neq 0$ is a tangent vector at any point of $G$, $d\varphi(\tau) \neq 0$.

Further, $G$ has the following universal property:

b. If $\{\varphi_t\}_{t \in T}$ is any algebraic family of automorphisms of $X$ such that $\varphi_t \in G$ for every $t \in T$, there is a unique morphism $\tilde{\varphi} : T \to G$
such that $\bar{\varphi}(t) = \varphi_t$.

We will first show that (a) implies (b), and this in turn trivially implies the uniqueness assertion of the theorem. By an earlier remark, the subset $\Gamma$ of $T \times G$ consisting of those $(t, \varphi)$ for which $\varphi_t = \varphi$ is a closed subset of $T \times G$. Since this is precisely the graph of $\bar{\varphi}$, we have only to verify that the projection is an isomorphism. We shall prove that the differential map of the projection of $\Gamma$ onto $T$ is injective at every point of $\Gamma$. Let $p_1$ and $p_2$ be the projections of $\Gamma$ onto $T$ and $G$ respectively. Let $\{\psi_\gamma\}_{\gamma \in \Gamma}$ be the algebraic family on $X$ defined by $\psi_\gamma = \varphi_{p_1(\gamma)} = p_2(\gamma)$. If $\tau$ is any tangent vector at a point $\gamma_0$ to $\Gamma$, we have evidently $d\psi(\tau) = d\psi(dp_1(\tau)) = d\chi(dp_2(\tau))$. It follows by (a) that if $dp_1(\tau) = 0$, then $dp_2(\tau) = 0$ and hence $\tau = 0$.

By Lemmas 1 and 2 below and Zariski’s main theorem, we can find $y_1, \ldots, y_m \in X$ such that the morphism $\lambda : G \to X^m$ defined by $\lambda(g) = (gy_1, \ldots, gy_m)$ is a radical covering of the non-singular locally closed subvariety $W = \lambda(G)$ of $X^m$ by $G$. Since $\mu : T \to W$ given by $\mu(t) = (\varphi_t(y_1), \ldots, \varphi_t(y_m))$ is a morphism, its graph $\Gamma_\mu \subset T \times W$ is closed irreducible. Since $I_T \times \lambda : T \times G \to T \times W$ is a radical covering and $(I_T \times \lambda)^{-1}(\Gamma_\mu) = \Gamma$, $\Gamma$ is irreducible and $\Gamma \to T$ is proper. We may now apply the result of [5, Appendix to Exposé 5, p. 5-28] to conclude that $\Gamma \xrightarrow{p_1} T$ is an isomorphism, and $\bar{\varphi} = p_2 \circ p_1^{-1}$ is the required morphism.

Hence we have only to construct a structure of variety on $G$ satisfying (a).

**Lemma 1.** Let $\{\varphi_t\}_{t \in T}$ be an algebraic family of automorphisms of a variety $X$ parametrised by a (not necessarily irreducible) algebraic space $T$. Then there exists a finite number of points $x_1, \ldots, x_n \in X$ such that if $\varphi_t(x_i) = \varphi_{t'}(x_i)$ ($i = 1, \ldots, n; t, t' \in T$), then $\varphi_t = \varphi_{t'}$.

**Proof.** For any $x \in X$, let $S_x$ be the closed subset of $T \times T$ consisting of all $(t, t')$ such that $\varphi_t(x) = \varphi_{t'}(x)$ and $S$ the subset of $(t, t')$ such that $\varphi_t = \varphi_{t'}$. Then we have $S = \bigcap_{x \in X} S_x$, and since $T \times T$ is a noetherian space, $S = \bigcap_{i=1}^n S_{x_i}$, where $x_1, \ldots, x_n$ are a finite number of points of $X$. This is the assertion of the lemma. $\square$
Lemma 2. Let $G$ be a connected group of automorphisms of a variety $X$, and $x$ any point of $X$. Then the orbit $Gx = \{ \varphi(x) | \varphi \in G \}$ is a locally closed non-singular subvariety of $X$. Moreover if $G$ is finite dimensional, $\dim Gx \leq \dim G$.

Proof. By a well known theorem of Chevalley, if $\{ \varphi_t \}_{t \in T}$ is any algebraic family of automorphisms of $X$, the subset $\varphi_T(x) = \{ \varphi_t(x) | t \in T \}$ is an irreducible constructible subset of $X$ of dimension at most equal to the dimension of $X$. It follows that we can choose a family $\{ \varphi_t \}_{t \in T}$ such that $\varphi_t \in G$ for all $t \in T$ and $\dim \varphi_T(x)$ is a maximal. By replacing this family by $\{ \varphi_t \circ \varphi_{t_0}^{-1} \}_{t \in T}$, if necessary, we may assume that $\varphi_{t_0}$ is the identity of $X$ for some $t_0 \in T$. The closure $\overline{\varphi_T(x)}$ of $\varphi_T(x)$ is a closed irreducible subvariety of $X$ and $\varphi_T(x)$ contains an open subset $U$ of $\overline{\varphi_T(x)}$. We assert that $Gx \subset \overline{\varphi_T(x)}$. If not, there would exist a $\psi \in G$ such that $\psi(x) \notin \varphi_T(x)$. Since $G$ is connected, there exists a family $\{ \psi_s \}_{s \in S}$ such that for two points $s_0, s_1 \in S$, we have $\psi_{s_0} = I_X, \psi_{s_1} = \psi$. The algebraic family of automorphisms $\{ \psi_t \circ \psi_s \mid (t, s) \in T \times S \}$ is contained in $G$, and contains both the families $\{ \varphi_t \}_{t \in T}$ and $\{ \psi_s \}_{s \in S}$. Hence it follows that $\varphi_T(x) \subsetneq \varphi_T \circ \psi_S(x)$ (since $\psi_{S_1}(x) \notin \varphi_T(x)$), $\dim \varphi_T \circ \psi_S(x) = \dim \varphi_T \circ \psi_T(x) > \dim \varphi_T(x)$, which contradicts our choice of the family $\{ \varphi_t \}$.

Thus, $Gx \subset \varphi_T(x)$, and since $Gx = \bigcup_{\varphi \in G} \varphi(U)$ and each $\varphi(U)$ is open in $\varphi_T(x)$, $Gx$ is open in $\varphi_T(x) = Gx$. Hence $Gx$ is locally closed in $X$, and since $G$ acts transitively on the variety $Gx$, it is non-singular.

Suppose now that $G$ is of finite dimension $N$, and $\dim Gx > N$. It follows from the first part of the proof that there is an algebraic family $\{ \varphi_t \}_{t \in T}$ contained in $G$ such that $\dim \varphi_T(x) = \dim Gx > N$. Since the morphism $T \rightarrow Gx$ given by $t \rightarrow \varphi_t(x)$ is dominant, it is easy to see that there is a subvariety $T_1$ of $T$ such that $\dim T_1 = \dim Gx$ and the morphism $T_1 \rightarrow Gx$ given by $t_1 \rightarrow \varphi_{t_1}(x)$ is again dominant. The function field $R(T_1)$ of $T_1$ is therefore algebraic over the function field $R(Gx)$ of $Gx$. Hence, by replacing $T_1$ by an open subset, we may further assume that the fibers of the morphism $t_1 \rightarrow \varphi_{t_1}(x)$ are finite, and in particular that for any $t_1 \in T_1$, there are only a finite number of $t_2 \in T_1$ such that $\varphi_{t_1} = \varphi_{t_2}$. If we can construct by a suitable “descent” an
injective family of automorphisms of the same dimension, we would have the required contradiction.

By Lemma 1 there exist \(y_1, \ldots, y_n \in X\) such that \(\varphi_{t_1}(y_i) = \varphi_{t_2}(y_i)\) \((i = 1, \ldots, n)\) implies that \(\varphi_{t_1} = \varphi_{t_2}\). Let \(y = (y_1, \ldots, y_n) \in X^n\), and let \(\varphi^n_{t_1}, \varphi^n_{t_2}\) be the algebraic family of automorphisms of \(X^n\) defined by \(\varphi^n_{t_1}(x_1, \ldots, x_n) = (\varphi_{t_1}(x_1), \ldots, \varphi_{t_1}(x_n))\). Since \(\varphi^n_{T_1}(y)\) is constructible we may assume that \(\varphi^n_{T_1}(y)\) is actually a locally closed normal subvariety of \(X^n\), by replacing \(T_1\) by an open subset. Since the fibers of \(t_1 \rightarrow \varphi^n_{T_1}(y)\) are finite, we may assume (by replacing \(T_1\) by its normalisation in a normal algebraic extension of \(R(\varphi^n_{T_1}(y))\) containing \(R(T_1)\)) that \(R(T_1)\) is normal over \(R(\varphi^n_{T_1}(y))\). Let \(T'_1\) be the normalisation of \(\varphi^n_{T_1}(y)\) in the purely inseparable closure of \(R(\varphi^n_{T_1}(y))\) in \(R(T_1)\). By replacing by an open subset, we may assume that the morphism \(T_1 \rightarrow T'_1\) is a Galois covering, so that \(T_1\) is the quotient of \(T'_1\) by a finite group \(\prod\). If \(t_1, t_2 \in T_1\) have the same image in \(T'_1\), then \(\varphi^n_{t_1}(y) = \varphi^n_{t_2}(y)\) and hence \(\varphi_{t_1} = \varphi_{t_2}\), and conversely, if \(\varphi_{t_1} = \varphi_{t_2}\), \(\varphi^n_{t_1}(y) = \varphi^n_{t_2}(y)\) and hence \(\lambda(t_1) = \lambda(t_2)\) since \(T'_1\) is a purely inseparable covering of an open subset of \(\varphi^n_{T_1}(y)\). Thus, the defining morphism \(\varphi : T_1 \times X \rightarrow X\) commutes with the action of \(\prod\) on \(T_1 \times X\), and hence “passes down” to a morphism \(\varphi' : T'_1 \times X \rightarrow X\) such that \(\varphi' \circ (\lambda \times 1_X) = \varphi\). Then \(\varphi'\) defines an injective algebraic family of dimension = dimension of \(T_1 > N\), which is a contradiction.

Lemma 2 is proved.

We now proceed to the proof of the theorem. Let \(\{\varphi_t\}_{t \in T}\) be an injective family contained in \(G\) and containing the identity such that \(\dim T = \dim G\) and \(T\) is normal. We assert that any element \(\psi\) of \(G\) can be written as \(\varphi_{t_1} \circ \varphi_{t_2}^{-1}\) with \(t_1, t_2 \in T\). In fact, by an application of Lemma 1 to the union of the two families \(\{\varphi_t\}_{t \in T}\) and \(\{\psi \circ \varphi_t\}_{t \in T}\), we deduce that there exist a finite number of points \(x_1, \ldots, x_n\) such that \(\varphi_t(x_i) = \varphi_{t'}(x_i)\) implies that \(\varphi_t = \varphi_{t'}\) and also such that \(\varphi_t(x_i) = \psi \circ \varphi_{t'}(x_i)\) implies that \(\varphi_t = \psi \circ \varphi_{t'}\). Let \(x = (x_1, \ldots, x_n) \in X^n\), and make \(G\) act on \(X^n\) componentwise. Then \(Gx\) is an irreducible locally closed subvariety of \(X^n\) whose dimension is the dimension \(N\) of \(G\), by Lemma 2 and because the morphism \(t \rightarrow \varphi^n_T(x)\) of \(T\) into \(Gx\) is injective. Also \(\varphi^n_T(x)\) and \(\psi \circ \varphi^n_T(x)\)
contain open subsets of $Gx$, since both are of dimension $N$. Hence these two subsets of $Gx$ have a non-void intersection, so that $\varphi_{t_1}^n(x) = \psi \circ \varphi_{t_2}^n(x)$ for some $t_1, t_2 \in T$, which implies (by our choice of $x$) that $\varphi_{t_1}^n = \psi \circ \varphi_{t_2}$, $\psi = \varphi_{t_1} \circ \varphi_{t_2}^{-1}$. Thus the algebraic family $\{\varphi_{t\cdot t} \circ \varphi_{t_2}^{-1}\}_{(t, t') \in T \times T}$ contains all the elements of $G$. Hence by Lemma 1, there exist a finite number of points $y_1, \ldots, y_m \in X$ such that $\varphi(y_i) = \varphi'(y_i) (i = 1, \ldots, m)$, $\varphi, \varphi' \in G$, implies that $\varphi = \varphi'$.

Let $y$ be the point $(y_1, \ldots, y_m) \in X_m$, and $Gy$ the orbit of $y$ for the action of $G$ componentwise on $X^m$. It follows from Lemma 2 that $Gy$ is an irreducible locally closed non-singular subvariety of $X_m$ of dimension $N$. Since the morphism $T \to Gy$ given by $t \to \varphi_t(y)$ is dominant and injective, $R(T)$ is purely inseparable over $R(Gy)$. If the characteristic is zero, it follows from Zariski’s main theorem that $T$ is isomorphic to an open subset of $Gy$, and we put $Z = Gy$. If the characteristic is $p > 0$, we can find an integer $n \geq 0$ such that $R(T) \subset R(Gy)^{p^n}$. In this case, let $Z$ be the normalisation of $Gy$ in $R(Gy)^{p^n}$. By replacing $T$ by its normalisation in $R(Gy)^{p^n}$ we may assume that $T$ is an open subset of $Z$. Let $\pi : Z \to Gy$ denote the projection of $Z$ onto $Gy$ (and the identity map if characteristic is zero). Since $Z$ is the normalisation of $Gy$ in $R(Gy)^{p^n}$, and since $G$ acts (as an abstract group) as a group of automorphisms of $Gy$, it can be made to act as a group of automorphisms of $Z$ in such a way as to commute with the projection $\pi$. Since $\pi$ is bijective, it follows from our choice of $y$ that for any $z \in Z$, there is a unique element $\varphi_z \in G$ such that $\varphi_z(y) = \pi(z)$, and it follows that for any $\psi \in G$, we have $\varphi_{\psi z} = \psi \circ \varphi_z$. Also the map of $Z$ onto $G$ given by $z \to \varphi_z$ is a bijection. Since the family of automorphisms $\{\varphi_z\}_{z \in Z}$ is algebraic when restricted to the open subset $T$, and since $G$ acts transitively (and simply) as a group of automorphisms of $Z$, it follows that $\{\varphi_z\}_{z \in Z}$ is an algebraic family.

We have thus constructed an algebraic family $\{\varphi_z\}_{z \in Z}$ parametrised by a non-singular variety $Z$, such that (a) $z \to \varphi_z$ is a bijection of $Z$ onto $G$, and (b) $G$ (as an abstract group) acts on $Z$ in such a way that for $\psi \in G, z \in Z$, we have $\varphi_{\psi z} = \psi \circ \varphi$. If the family $\{\varphi_z\}_{z \in Z}$ is infinitesimally injective (this always holds when the characteristic of $K$ is zero, as is well known) on the whole of $Z$, we transport the algebraic structure of $Z$.
onto $G$ by the above bijection, and we are through. Suppose that this is not so, so that the characteristic $p$ of $K$ is $> 0$. At any point $z \in Z$, let $T_z$ be the tangent space of $Z$, and let $T'_z$ be the kernel of the linear map $d\varphi$ of $T_z$ into the space of vector fields on $X$. Because of (b), the dimension of $T'_z$ is the same for all $z \in Z$. Since locally on $Z$ $T'_z$ is defined by the vanishing of a finite number of regular differential forms, it follows that the family of vector spaces $\{ T'_z \}_{z \in Z}$ defines a sub-bundle $T'$ of the tangent bundle of $Z$. It is easy to verify that if $X$ and $Y$ are vector fields on an open set of $Z$ such that their values at any point $z$ of this open set belong to $T'_z$, the same is true of $[X, Y]$ and $X^p$. Thus, $T'$ is an integrable sub-bundle of the tangent bundle of $Z$, in the sense of Cartier (see Exposé 6 of [5]). Hence there exists a non-singular variety $Z'$ and a radicial covering $p : Z \to Z'$ of height one such that the kernel of $dp$ at any $z \in Z$ is precisely $T'_z$. Further, there exists a morphism $\varphi' : Z' \times X \to X$ such that $\varphi' \circ (p \times I_X) = \varphi$ (Theorem 2 and Proposition 7, Exposé 6, [5]). Thus, the family $\{ \varphi'_z \}_{z \in Z'}$ parametrised by $Z'$ and defined by $\varphi'_{p(z)} = \varphi_z$ for $z \in Z$ is again algebraic. Also the action of $G$ on $Z$ “goes down” to an action of $G$ on $Z'$ since it leaves the sub-bundle $T'$ invariant. Finally we have a morphism of $Z'$ onto $Gy$ defined by $z' \to \varphi'_z(y)$, which implies that $R(Z) \supseteq R(Z') \supseteq R(Gy)$, $[R(Z) : R(Z')] > 1$. If the family on $Z'$ is not infinitesimally injective, we may repeat the above method of descent, to get a $Z''$ with $R(Z) \supseteq R(Z') \supseteq R(Z'') \supseteq R(Gy)$, $[R(Z') : R(Z'')] > 1$. Since $[R(Z) : R(Gy)] < \infty$, we must arrive at a bijective and infinitesimally injective algebraic family in a finite number of steps. Transporting the algebraic structure of the parametrising variety of this family to $G$, we arrive at a structure of an algebraic variety on $G$, such that $G \times X \xrightarrow{\chi} X$ defined by $\chi(\varphi, x) = \varphi(x)$ is a morphism and the family $\{ \chi_\varphi \}_{\varphi \in G} (\chi_\varphi = \varphi)$ is infinitesimally injective.

Now, in the proof of the fact that part (a) of the theorem implies (b), we never used the fact that the group operations on $G$ are algebraic. Thus we may apply (b) to the algebraic family $\{ \chi_\varphi \circ \chi_\varphi^{-1} \}_{(\varphi, \varphi') \in G \times G}$ to deduce that the map $G \times G \to G$ given by $(\varphi, \varphi') \to \varphi \circ \varphi'^{-1}$ is a morphism.

The theorem is completely proved.

We now apply the theorem to the group of all automorphisms of a
semi-complete variety which can be connected to the identity automorphism by an algebraic family parametrised by an irreducible variety. (From the preliminary remarks made at the beginning of this note, it follows that such automorphisms form a group under composition.) We shall say that a variety $X$ is semi-complete if for any torsion free coherent algebraic sheaf $\mathcal{F}$ on $X$, the vector space $H^0(X, \mathcal{F})$ (over $K$) of sections is finite dimensional. By the theorem, we have only to show that there exists an integer $N$ such that if $\{\varphi_t\}_{t \in T}$ is any injective algebraic family of automorphisms of $X$, $\dim T \leq N$. The normalization $(\tilde{X}, p)$ of $X$ is again semi-complete; for if $\mathcal{F}$ is coherent and torsion free on $\tilde{X}$, its direct image $p_*(\mathcal{F})$ on $X$ is again coherent and torsion free, and $H^0(\tilde{X}, \mathcal{F}) \cong H^0(X, p_*(\mathcal{F}))$. Also the family $\{\varphi_t\}_{t \in T}$ lifts to a family $\{\tilde{\varphi}_t\}_{t \in T}$ of automorphisms of $\tilde{X}$, which is again injective. Let $Y$ be the closed set of singular points of $\tilde{X}$. Then any automorphism of $\tilde{X}$ leaves $\tilde{X} - Y$ stable. Any coherent torsion free sheaf $\mathcal{F}_1$ on $\tilde{X} - Y$ admits of an extension $\mathcal{F}$ to $\tilde{X}$, which is again torsion free, and since $\tilde{X}$ is normal and codim $Y \geq 2$, it follows that the map $H^0(\tilde{X}, \mathcal{F}) \cong H^0(\tilde{X} - Y, \mathcal{F}_1)$ is an isomorphism.

Thus, we are reduced to the case of a non-singular semi-complete variety $X$. In this case, it is well known that the group of coherent sheaves of principal ideals on $X$ (the Cartier divisors) is canonically isomorphic to the free group generated by the subvarieties of codimension one in $X$. Let $f_1, \ldots, f_p$ be non-constant rational functions on $X$ generating the function field $R(X)$ over $K$, and let $D = \sum_{j=1}^n D_j$ be any positive divisor on $X$ with $D_j$ prime, such that $D + \text{div}(f_i) \geq 0$, and $D + \text{div}(f_i - 1) \geq 0$. If $\{\varphi_t\}_{t \in T}$ is any algebraic family of automorphisms of $X$ such that for some $t_0 \in T$, $\varphi_{t_0} = \text{Identity}$ and for any $t \in T$, the inverse image $\varphi_t^*(D)$ of $D$ equals $D$, I assert that $\varphi_t = \text{Identity}$. In fact, since $T$ is irreducible, it follows that we must have $\varphi_t(D_j) = D_j$ for any $j$, $1 \leq j \leq n$. If $V_j$ is the discrete valuation on $R(X)$ defined by $D_j$, it follows that $V_j(f \circ \varphi_t) = V_j(f)$. Hence, we must have $\text{div}(f_i) = \text{div}(f_i \circ \varphi_t)$, $\text{div}((f_i - 1) \circ \varphi_t) = \text{div}(f_i - 1)$ for $1 \leq i \leq p$. Since $X$ is semi-complete, the functions $\frac{f_i \circ \varphi_t}{f_i}$ and $\frac{(f_i - 1) \circ \varphi_t}{f_i - 1}$, being everywhere regular, must
be constants. Thus we obtain
\[ f_i \odot \varphi_t = a_i f_i, \]
\[ (f_i - 1) \odot \varphi_t = b_i(f_i - 1) = f_i \odot \varphi_t - 1 = a_i f_i - 1, \]
which shows that \( a_i = b_i = 1 \) and \( f_i \odot \varphi_t = f_i \). Thus, \( \varphi_t \) induces the identity automorphism on \( R(X) \), and hence must be the identity.

Now if \( \{ \varphi_t \}_{t \in T} \) is any irreducible algebraic family of automorphisms of \( X \) with \( \varphi_{t_0} = \text{Identity} \), \( \{ \varphi_t^*(D) \}_{t \in T} \) is an algebraic family of divisors on \( X \) with \( \varphi_{t_0}^*(D) = D \). If \( \text{Pic}(X) \) is the (connected) Picard variety of \( X \), we thus get a morphism \( \psi : T \to \text{Pic}(X) \) defined by \( \psi(t) = \text{Cl}(\varphi_t^*(D) - D) \) ([5], Exposé 8, corollary to Theorem 3). Let \( T_1 \) be an irreducible component of \( \psi^{-1}(\psi(t_0)) \) containing \( t_0 \). We then have \( \dim T \leq \dim T_1 + \dim \text{Pic}(X) \), by the dimension theorem ([1], Chapter III, Theorem 2). But now, for every \( t \in T_1 \), \( \varphi_t^*(D) - D \) is linearly equivalent to zero, and thus we have an injective morphism \( \xi : T_1 \to P^r \), where \( P^r \) is the projective space which parametrises the complete linear system containing \( D \) ([5], corollary to Prop. 7 and Theorem 2, Exposé 5]). Hence, we deduce that \( \dim T \leq \dim |D| + \dim \text{Pic}(X) \).

We have thus proved

**Corollary 1.** Let \( X \) be a semi-complete variety. Then the group \( G \) of all automorphisms of \( X \) which can be connected to the identity automorphism by an irreducible family can be given the structure of a group variety such that the map \( G \times X \to X \) given by \( (\varphi, x) \to \varphi(x) \) is a morphism. The induced linear map of the Lie algebra \( \mathfrak{g} \) of \( G \) into the (finite dimensional) vector space of regular vector fields on \( X \) is an injection. \( G \) has the universal mapping property for all irreducible algebraic families of automorphisms containing the identity.

**Remark.** By substituting \( G \) for \( T \) in the argument preceding the corollary, we see that \( G \) is an extension of a subgroup of \( \text{Pic}(X) \) by a linear group. In particular, when \( \text{Pic}(X) \) is trivial, \( G \) is a subgroup of the projective group of the projective space which defines the linear system \( |D| \). Further, when \( X \) is itself projective, we may clearly assume (by adding to \( D \) a high multiple of an ample divisor) that \( D \) is a hyperplane section
in a projective imbedding of $X$. It follows that $G$ is the restriction to $X$ of a group of projective transformations of the ambient projective space (for this projective imbedding).

Now, let $P$ be a locally isotrivial principal fiber space over a complete variety $X$ with structure group $G$. ([6], Exposé 1, §2.2.) We will show that the group $H$ of automorphisms of $P$ which commute with the action of $G$ on $P$ and which can be connected to the identity automorphism of $P$ is finite dimensional. Let $q : P \to X$ be the projection. If $\{\varphi_t\}_{t \in T}$ is any injective algebraic family of automorphisms of $P$ with $\varphi_{t_0} = \text{Identity}$ for some $t_0 \in T$, it is easy to check that it induces an algebraic family of automorphisms $\{\bar{\varphi}_t\}_{t \in T}$ of $X$ such that $q \circ \varphi_t = \bar{\varphi}_t \circ q$. By Corollary 1 and the dimension theorem, it is sufficient to bound the dimension of any algebraic family $\{\varphi_t\}_{t \in T}$ such that $\varphi_{t_0} = \text{Identity}$ and $q(\varphi_t(x)) = q(x)$, that is, a family which fixes the base space.

Let $\varphi$ be any automorphism of $P$ which is identity on $X$, so that for any $p \in P$, there is a unique $\psi(p) \in G$ such that $\varphi(p) = p\psi(p)$. Then $\psi$ is a morphism of $P$ into $G$ satisfying $\psi(pg) = g^{-1}\psi(p)g$. Let $Ad(P)$ denote the bundle associated to $P$ with fiber $G$ for the action of $G$ on the left of $G$ by inner automorphisms and $\eta : P \times G \to Ad(P)$ the canonical map ([6], Exposé 1, §3.3). There is then a unique regular section $\sigma : X \to Ad(P)$ such that $\eta(p, \psi(p)) = \sigma(q(p))$. Suppose now that $H$ is a closed normal subgroup of $G$, and let $P'$ be the principal fiber space with structure group $G/H$ deduced from $G$ ([6], Exposé 1, §3.3). It is clear that $\varphi$ induces an automorphism of $P'$, which is the identity if and only if the morphism $\psi : P \to G$ defined above maps $P$ into $H$, or equivalently, if the section $\sigma$ of the bundle $Ad(P)$ has values in the sub-bundle with fiber $H$.

Assume first that the structure group $G$ is linear, so that we may assume it to be a subgroup of a full linear group $Gl(n)$. Let $G$ act on the vector space $M(n)$ of all $(n, n)$ matrices on the left by inner automorphisms, and let $V$ be the associated vector bundle. Then $Ad(P)$ is a sub-bundle of $V$. If $\{\varphi_t\}_{t \in T}$ is an injective family of automorphisms of $P$, we therefore get for each $t \in T$ a section $\sigma_t : X \to V$ of $V$, and it is easy to see that $\sigma : T \times X \to V$ defined by $\sigma(t, x) = \sigma_t(x)$ is a
morphism. Since $X$ is complete, the vector space $\mathcal{L}$ of sections of $V$ is finite dimensional, and if $\mathcal{L}$ is provided with the structure of an affine space, $t \in T \to \sigma_t \in \mathcal{L}$ is clearly a morphism which is injective. Hence $\dim T \leq \dim_K \mathcal{L}$, and we are through in this case.

Next suppose $G$ is any connected algebraic group, and $C$ the centre $G$. Then $G/C$ is a linear group ([4], §4, Lemma 3). Since we know the finite dimensionality of the group of automorphisms of the principal bundle with group $G/C$ deduced from $P$, it is sufficient to prove the finite dimensionality of the group of automorphisms of $P$ which induce the identity on the base and on the associated bundle with $G/C$ as fiber. If $\{\varphi_t\}_{t \in T}$ is any injective family of automorphisms of this group with $\varphi_{t_0} = \text{Identity}$, we get a morphism $\sigma : T \times X \to C$ such that if $\sigma_t : X \to C$ is defined by $\sigma_t(x) = \sigma(t, x)$, $\sigma_t \neq \sigma_{t'}$ if $t \neq t'$, since the bundle associated to $P$ with fiber $C$ and the (trivial) action of $G$ on $C$ by inner automorphisms is trivial. Also we have $\sigma_{t_0}(X) = e$ in $C$. Let $C'$ be the maximal linear subgroup of $C$, so that $C/C'$, is an abelian variety, and $j : C \to C/C'$ the canonical homomorphism. Since $j \circ \sigma(t_0 \times X) = e$ in $C/C'$, it follows from well known theorems on abelian varieties that $j \circ \sigma$ depends only on $T$, that is, there is a morphism $\xi : T \to C/C'$ such that $j \circ \sigma(t, x) = \xi(t)$. Hence if $T_1$ is any irreducible component of $\xi^{-1}(e)$ containing $t_0$, $\dim T \leq T_1 + \dim C/C'$. But for any $t \in T_1$, $\sigma_t(X) \subset C'$, and since $X$ is complete and $C'$ is linear, $\sigma_t(X)$ is a single point $\sigma_t \in C'$, and the morphism $T_1 \to C'$ given by $t \to \sigma_t$ is injective. Hence, $\dim T \leq \dim C' + \dim C/C'$.

Finally, suppose $G$ is not connected, and let $G_0$ be the connected component of $G$ containing $e$. Then $P$ may be considered as a principal bundle with structure group $G_0$ over the Galois covering $Y = P \times^G G/G_0$ of $X$. Any connected family of automorphisms of $P$ over $X$ induces the identity on $Y$, and hence may be considered as a family of automorphisms of $P$ over $Y$. Since $Y$ is again complete we are reduced to the previous case.

Thus, we have proved

**Corollary 2.** Let $P$ be a locally isotrivial principal fiber space with base a complete variety $X$ and structure group $G$. Let $\text{Aut}^0(P)$ be the group
of all automorphisms of $P$ which can be connected to the identity by an irreducible algebraic family, and $\text{Aut}^0_X(P)$ the subgroup of $\text{Aut}^0(P)$ consisting of those automorphisms which leave the base fixed. Then $\text{Aut}^0_X(P)$ can be made into an algebraic group variety in such a way that the map $\chi : \text{Aut}^0(P) \times P \to P$ defined by $\chi(\varphi, p) = \varphi(p)$ is a morphism. $\text{Aut}^0_X(P)$ is a closed subgroup of $\text{Aut}^0(P)$. The linear map $d_\chi$ maps the tangent space at $e$ to $\text{Aut}^0(P)$ (resp. $\text{Aut}^0_X(P)$) injectively into the vector space of $G$-invariant vector fields on $P$ (resp. $G$-invariant vector fields on $P$ which are tangential to the fiber at any point of $P$).

On a Certain Purity Theorem

By C.P. Ramanujam

[Received May 1, 1970]

1 Statement of result

Let $X$ and $Y$ be connected complex manifolds and $f : X \to Y$ a proper and flat holomorphic map. Let $D \subset X$ be the analytic set where the differential $df$ is not of maximal rank and $E = f(D)$ the set of critical values of $f$. It has been conjectured that $E$ is pure of codimension one in $Y$. This has been proved by I. Dolgacev [1] and R. R. Simha [2] when the general fibre is a compact Riemann surface of genus $g \geq 1$. We prove the conjecture when the general fibre is the Riemann sphere, thereby establishing the conjecture when the relative dimension $\dim X - \dim Y$ is one. (When the general fibre is not connected, use Stein factorisation and purity of branch-locus).

Specifically, we prove the following

**Theorem.** Let $X$, $Y$ be connected complex manifolds, $f : X \to Y$ a proper flat holomorphic map such that the general fibre of $f$ is the Riemann sphere, $D$ the set points in $X$ where $df$ is not of maximal rank and $E = f(D)$. Then $E$ is pure of codimension one in $Y$.

---

1Since $X$ and $Y$ are manifolds and $f$ is proper, the assumption of flatness is equivalent to the assumptions that $f$ is surjective and that all the fibres of $f$ are of the same dimension everywhere on $X$. 

87
2 Proof of Theorem

Let us assume to the contrary that the analytic set $E$ is not pure of codimension one. We first achieve several reductions, which are valid even when the general fibre is only assumed of dimension one.

Firstly, since the set of $(n, n + 1)$ matrices not of maximal rank is an analytic subset pure of codimension 2 in the space of all $(n, n + 1)$ matrices, it follows that any irreducible component of $D$ is of codimension $\leq 2$ in $X$, hence any component of $E$ is of codimension $\leq 2$ in $Y$. Thus if $E$ is not pure of codimension one, by removing a certain analytic set from $Y$, we may assume that $E$ is a connected sub-manifold of codimension two in $Y$.

Next, let $D' = \{x \in X \mid \text{rank}(df)_x \leq \dim Y - 3\}$. We assert that $\dim D' \leq \dim X - 3$. If not, $D'$ has an irreducible component $Z$ of codimension $\leq 2$ in $X$, and there would exist an open subset $U$ of $Z$ of smooth points $x$ where $\dim(\ker(df)_x \cap T_x(U)) \geq 2$, so that there would exist a holomorphic vector field on a non-void open subset $U'$ of $U$, not tangential to the fibres of $f$ but mapped to zero by $df$. This is clearly impossible, since the restriction of $f$ to any integral curve of this vector field must be constant. Also, we see that if $Z$ is a component of $D'$ of dimension equal to $\dim X - 3$, at any regular point of $Z$, $\ker df[Z] \neq 0$, so that dimension $f(Z) \leq \dim Y - 3$. Hence, by throwing out $f(D')$ from $Y$, we may assume that $\text{rank}(df) \geq \dim Y - 2$ everywhere on $X$.

Let $D_i(1 \leq i \leq p)$ be the components of $D$, so that each $D_i$ is of codimension 2 in $X$ and $f(D_i) = E$. We can clearly choose a point $y \in E$ having the following properties: (i) every component of the fibre over $y$ of the map $f|D_i : D_i \to E$ meets the set $(D_i)_{\text{reg}}$ of smooth points of $D_i$, and (ii) on every component of the fibre over $y$ of the induced map $g_i : (D_i)_{\text{reg}} \to E$, $g_i$ is of maximal rank.

**Lemma.** For a dense subset $\Omega$ of the Grassmannian of two dimensional subspaces of the tangent space $T_y(Y)$ to $Y$ at $y$, we have

$$\text{Im}(df)_x + V = T_y(Y), \forall x \in f^{-1}(y), \forall V \in \Omega.$$  

**Proof.** Let $C_1, \ldots, C_q$ be the irreducible components of $f^{-1}(y) \cap D$. If for some $C_i$, $\text{rank}(df)_x = \dim Y - 2$ for all $x \in C_i$, by (i) and (ii) above,
we see that $\text{Im}(df)_x = T_y(E)$ for all $x \in C_i$. Then define $\Gamma_i$ to be the set of 2-dimensional subspaces of $T_y(Y)$ meeting $T_y(E)$ in a space of dimension $\geq 1$. On the other hand, suppose $C$ is a component such that $\text{rank}(df)$ is $\dim(Y) - 1$ generically on $C_i$. Then there is a finite set of points $x_1, \ldots, x_r$ on $C_i$ such that $\text{rank}(df)_{x_j} = \dim Y - 2$ and $\text{rank}(df)_x = \dim Y - 1$ for $x \in C_i$, $x \neq x_j$ for any $j$. Let $\sum_j$ be the set of 2-dimensional subspaces of $T_y(Y)$ contained in $\text{Im}(df)_{x_j}$ for some $x \in C_i \setminus \{x_1, \ldots, x_r\}$. Put $\Gamma_i = \sum' \cup \bigcup_j \sum_j$.

A simple argument (counting constants) shows that each $\Gamma_i$ and hence $\Gamma = \bigcup \Gamma_i$ is a countable union of closed nowhere dense subsets of the Grassmannian of 2-dimensional subspaces of $T_y(Y)$. Hence if $\Omega$ is the complement of $\Gamma$ in this Grassmannian, $\Omega$ has the required property.

Now for the next reduction. Choose $y \in E$ as above, and a 2-dimensional subspace $V$ of $T_y(Y)$ transversal to $T_y(E)$ with $V \in \Omega$. Choose a submanifold $Y'$ of dimension two in a neighbourhood of $y$ meeting $E$ only at $y$ and having $V$ for its tangent space. Put $X' = f^{-1}(Y')$, so that $X'$ is a submanifold of $X$ proper and flat over $Y'$. Further, if $g : X' \to Y'$ is induced by $f$, $g$ is of maximal rank outside $g^{-1}(y)$. Now for any flat holomorphic map $\phi$ of complex manifolds, $\phi$ is of maximal rank along a fibre if and only if the “correct” fibre (as an analytic space, possibly with nilpotent elements in its structure sheaf, whose defining ideal sheaf is generated by the maximal ideal of the local ring of the point in the image space) is reduced and smooth. Now, the fibres of $f$ and $g$ over $y$ are the same, so that $g$ cannot be of maximal rank all along $g^{-1}(y)$.

We are thus reduced to the case where $Y$ is an open neighbourhood in $C^2$ of the closed ball $D_1 = \{(z_1, z_2) \in C^2 | |z_1|^2 + |z_2|^2 \leq 1\}$ and $E$ consists of the single point $0 \in C^2$. We now make use of the hypothesis that the general fibre (hence every fibre $f^{-1}(z)$ for $z \neq 0$) is holomorphically isomorphic to the Riemann sphere.

Now, we assert that the inclusion $f^{-1}(0) \hookrightarrow f^{-1}(D_1)$ is a homotopy equivalence. To see this, note that since $X$ can be triangulated such that $f^{-1}(0)$ is a sub-complex, there is a fundamental system of neighbour-
hoods \(\{U_n\}_{n \geq 1}\) of \(f^{-1}(0)\) such that \(f^{-1}(0)\) is a strong deformation retract of each \(U_n\). Further, if \(D_\epsilon\) is the closed disc of radius \(\epsilon < 1\) around 0 in \(C^2\), \(f^{-1}(D_\epsilon)\) is a strong deformation retract of \(f^{-1}(D_1)\). In fact, one can retract \(f^{-1}(D_1)\) to \(f^{-1}(D_\epsilon)\) along a projectable vector field on \(X\) whose projection to \(Y\) is an inward radial vector field around 0. Now, we have

\[
D_1 \supset U_p \supset D_\epsilon \supset U_q
\]

for some integers \(p, q > 0\) and some \(\epsilon\) with \(0 < \epsilon < 1\). Since \(U_p \supset U_q\) and \(D_\epsilon \subset D_1\) are homotopy equivalences, the inclusion \(U_q \hookrightarrow D_1\) induces isomorphisms of homotopy groups and is hence a homotopy equivalence. This proves the assertion.

Now, it is not difficult to show that \(f^{-1}(D_1 - (0)) \to D_1 - (0)\) is a holomorphic fibre bundle with fibre the Riemann sphere and structure group the projective group \(PGL(1, \mathbb{C})\). Since \(D_1 - (0)\) is of the homotopy type of \(S^3\) and \(\pi_2(PGL(1, \mathbb{C})) \approx \pi_2(SL(2, \mathbb{C})) \approx \pi_2(SU(2)) = \pi_2(S^3) = (e)\), this fibration is topologically trivial. Let \(M\) be the compact manifold \(f^{-1}(D_1)\) with boundary \(\partial M\) homeomorphic to \(S^2 \times S^3\). Now, \(f^{-1}(0)\) is the union of a number of irreducible one-dimensional compact analytic sets. Let \(v\) be this number. Then by Lefschetz duality, we have (with \(F = f^{-1}(0)\))

\[
Z^v \approx H_2(F) \approx H_2(M) \approx H^4(M, \partial M) \approx H^3(\partial M) \approx Z \Rightarrow v = 1,
\]

so that \(f^{-1}(0)\) is irreducible. Also,

\[
H_1(F) \approx H_1(M) \approx H^5(M, \partial M) \approx H^4(\partial M) = (0),
\]

so that \(F\) is locally irreducible (i.e., without nodes) at every point and the normalisation of \(F\) is the Riemann sphere.

Let \(m\) be the sheaf of ideals on \(Y\) defining the origin 0, and denote by \(F = f^{-1}(0)\) the “correct” fibre with structure sheaf \(\mathcal{O}_F = \mathcal{O}_X/m\mathcal{O}_X\). Since \(m\) is defined by two elements and \(F\) is of dimension one by the unmixedness theorem of Macaulay, the sheaf of ideals \(m\mathcal{O}_X\) has

---

\(^2\)All homologies, cohomologies are with integer coefficients. Further, \(H^*_c\) denotes cohomology with compact support.
On a Certain Purity Theorem

no embedded components at any point, hence is primary with radical the sheaf of prime ideals \( p \) defining the reduced fibre. Thus, if \( m\mathcal{O}_X \neq p \), that is if \( F \) is not reduced, we can find a series of ideals \( \mathcal{O}_F = a_0 \supset a_1 \supset \ldots \supset a_m = (0) \) such that each quotient \( a_i/a_{i+1} \) is an \( \mathcal{O}_X/p \)-module and

\[
\sum_i \ \text{Generic rank} \ \mathcal{O}_X/p \ (a_i, a_{i+1}) = r > 1.
\]

We now recall some “well-known” definitions. Let \( X, Y \) be connected complex manifolds and \( f : X \to Y \) a holomorphic map. Let \( Z \) be an irreducible closed analytic subset of \( Y \) of codimension \( p \) such that \( f^{-1}(Z) \) is pure of codimension \( p \). One then defines the analytic cycle (i.e., formal linear combination of closed irreducible analytic subsets) \( f^*(Z) \) in \( X \) to be \( \sum n_i C_i \) where \( C_i \) are the components of \( f^{-1}(Z) \) and \( n_i \) is defined as follows. Let \( q \) be the defining ideal of \( Z \). Then the sheaves \( \text{Tor}_r^{\mathcal{O}_Y}(\mathcal{O}_X, \mathcal{O}_Y/q) \) are coherent sheaves on \( X \) with support in \( f^{-1}(Z) \). On an open subset of \( C_i \), we can find coherent sheaves \( F_{r j} \),

\[
\text{Tor}_r^{\mathcal{O}_Y}(\mathcal{O}_X, \mathcal{O}_Y/q) = F_{r 0} \supset F_{r 1} \supset \ldots \supset F_{r n_r} = (0)
\]

such that \( F_{r j}/F_{r j+1} \) is an \( \mathcal{O}_{C_i} \)-module. Define the integer \( n_{ir} \) as

\[
n_{ir} = \sum \ \text{Generic rank on} \ C_i \ \text{of} \ F_{r j}/F_{r j+1}
\]

and put

\[
n_i = \sum (-1)^r n_{ir}
\]

Next, let \( X \) be a connected complex manifold and \( Z \) a compact irreducible analytic set on \( X \) of dimension \( r \). Then there is a unique generator \( \xi \in H_{2r}(Z) \approx Z \) determined by the orientation of \( Z \), since \( Z \) can be triangulated and is an oriented compact connected pseudomanifold of dimension \( 2r \) (see Seifert-Threlfall [3]). Let \( \xi' \) be the image of \( \xi \) in \( H_{2r}(X) \) and \( Cl(Z) \in H_c^{2(n-r)}(X) \), the Poincaré dual of \( \xi' \). We call \( Cl(Z) \) the cohomology class (with compact support) associated to \( Z \). If \( z_c^p(X) \) denotes the free abelian group on the irreducible compact analytic subsets of codimension \( p \), we obtain a homomorphism \( Cl : z_c^p(X) \to H_c^{2p}(X) \) on extending by linearity.
We then have the following (acceptable, “well-known” but nowhere explicitly proved) result (See remark at the end of the paper).

If \( f : X \to Y \) is a proper holomorphic map and \( Z \), a compact analytic irreducible subset of \( Y \) of codimension \( p \) such that \( f^*(Z) \) is defined, we have

\[
H_c^{2p}(f)(\text{Cl}(Z)) = \text{Cl}(f^*(Z))
\]

Now, let us return to our original situation. Let \( \mathring{D}_1 \) be the interior of \( D_1 \) and \( P \) any point of \( \mathring{D}_1 \). Then \( \text{Cl}(P) \in H_c^4(\mathring{D}_1) \) is the fundamental cohomology class with compact support of \( \mathring{D}_1 \). Put \( \mathring{M} = M - \partial M \), so that \( f|\mathring{M} : \mathring{M} \to \mathring{D}_1 \) is a proper holomorphic map. Since \( f \) is flat, \( H^i_{\partial Y}(\mathcal{O}_X, \mathcal{O}_Y/\mathcal{m}) = (0) \) for \( i > 0 \). Thus, if \( m\mathcal{O}_X \neq \mathcal{p} \), we see that \( f^*(0) \) is the cycle \( rF_0 \) where \( r \) is an integer > 1 and \( F_0 \) is the (reduced) fibre. By the result stated, \( H_c^4(f)(\xi) = r\text{Cl}(F_0) \) with \( r > 1 \). Now, consider the following commutative diagram

\[
\begin{array}{ccc}
Z \approx H^3(\partial M) & \xrightarrow{\beta_1} & H^4(M, \partial M) \\
\uparrow f_1^* & & \uparrow f_2^* \\
Z \approx H^3(S^3) & \xrightarrow{\alpha_1} & H^4(D_1, S^3) \\
\uparrow f_3^* & & \uparrow f_4^*
\end{array}
\]

where \( f_i^* \) are the maps induced by \( f \) in cohomology. Here, \( \alpha_1, \alpha_2 \) and \( \beta_2 \) are well-known to be isomorphisms, and \( f_1^* \) is an isomorphism since \( \partial M \to S^3 \) is a trivial fibration with fibre \( S^2 \). Finally, \( \beta_1 \) is also an isomorphism since \( H^3(M) = H^4(M) = (0) \). It follows that \( f_3^* \) is an isomorphism. Hence it cannot take a generator \( \xi \) of \( H_c^4(\mathring{D}_1) \) to an \( r \)-th multiple of an element of \( H_c^4(M) \) where \( r > 1 \).

This contradiction shows that \( m\mathcal{O}_X = \mathcal{p} \), so that \( F \) is a reduced (and irreducible) analytic set of dimension one. Since \( \chi(\mathcal{O}_{f^{-1}(z)}) = 1 \) for \( z \in Y, z \neq 0 \) and \( f \) is flat, we have \( \chi(\mathcal{O}_F) = 1 \) and \( H^1(F, \mathcal{O}_F) = (0) \). This implies that \( F \) is smooth (since singularities increase the arithmetic genus). By what was said earlier, \( f \) is of maximal rank along \( F \) which is a contradiction to our assumption that 0 is a critical value of \( f \). The theorem is proved. \( \square \)
Remark. The result stated about the naturality of $Cl$ with respect to proper maps is certainly reasonable, but nowhere explicitly proved to our knowledge. Borel-Haefliger [4] associate cohomology classes (with arbitrary support) to arbitrary (not necessarily compact) cycles, and prove naturality. Presumably their methods would also prove the above result. However, we prefer to give an ad hoc proof in our situation.

Let $P$ be a point of $f^{-1}(0)$ where the reduced fibre $F_{\text{red}}$ is smooth and choose a locally closed submanifold $Z$ of dimension 2 through $P$ transversal to the reduced fibre having $P$ as the unique point of intersection with $F$. By shrinking $D_1$ if necessary, we may assume that $Z \cap M$ is proper over $D_1$ with finite fibres. Since $Z$ and $F$ have intersection number one in the topological sense (Seifert-Threlfall [3]), using the well-known relationship between intersection of cycles and cup-product, we see that if $\alpha \in H^4_c(M) \approx H^4(M, \partial M)$ is the class associated to the reduced fibre and $\zeta \in H_4(M, \partial M)$ the cycle defined by $Z$, we have $\langle \alpha, \zeta \rangle = 1$. Now, the generator $\xi$ of $H^4(D_1, S^3) \approx H^4_c(\hat{D}_1)$ can be represented by a real 4-form $\omega$ with compact support in $\hat{D}_1$ and

$$\int_{\hat{D}_1} \omega = 1.$$ 

Since we have shown that $H^4(D_1, S^3) \to H^4(M, \partial M)$ is an isomorphism, $f^*(\omega)$ represents a generator of $H^4_c(\hat{M}) \approx H^4(M, \partial M)$. Thus, we see that $\alpha$ is the $\mu$-th multiple of the class of $f^*(\omega)$ in $H^4(M, \partial M)$ with $\mu \in \mathbb{Z}$. We thus obtain

$$1 = \langle \alpha, \zeta \rangle = \mu \int_{Z} f^*(\omega).$$ 

Now, if $m\mathcal{O}_X \neq p$, it is easy to see that $m$ together with the principal ideal in $\mathcal{O}_{P, X}$ defining $Z$ cannot generate the maximal ideal of $\mathcal{O}_{P, X}$. Hence, $f|Z : Z \to Y$ is not an isomorphism at $P$. By local analytic geometry, there is a neighborhood of 0 in $Y$, which we may assume to be $\hat{D}_1$, such that outside of a proper analytic subset of this neighborhood, $f|Z$ is a
covering of degree $r > 1$. Hence,

$$1 = \mu \int_{Z \cap \hat{M}} f^*(\omega) = \mu r \int_{D_1} \omega = \mu r$$

which shows that $\mu = r = 1$, a contradiction. This completes the proof.

Addendum. It was pointed out to us in a letter by R. R. Simha that the appeal to the theorem on the continuity of the Euler characteristic at the end of the proof of the theorem is unnecessary, since, once we know that the special fibre is reduced, the set of points where $f$ is not of maximal rank is of codimension $\geq 3$, and hence is empty.

This enables us to extend the proof also to the case when the general fibre is a non-singular curve of arbitrary genus. In fact, in the notation of the above proof, we have only to show that $H^4_c(\hat{D}_1) \rightarrow H^4_c(\hat{M})$ is surjective (hence an isomorphism, since $\text{Rank } H^4_c(\hat{M}) \geq 1$). The rest of the proof does not utilise the genus zero assumption. By the Wang sequence of the fibration $\partial M \rightarrow S^3$, we see that $H^3(S^3) \rightarrow H^3(\partial M)$ is surjective and since $H^4(M) = 0$, $H^1(\partial M) \rightarrow H^4(M, \partial M) = H^4_c(\hat{M})$ is also surjective. This proves the assertion, and we get a uniform proof for all genera.

Added in Proof (Nov. 16, 1970)

The author is informed that the result has also been proved in the case of algebraic varieties when the genus of the general fibre is zero, by I. Dolgacev and M. Raynaud.

The following very simple counter-example to the conjecture when the dimension of the fibre is $\geq 2$ was pointed out by Professor David Mumford.

Let $X$ be a compact non-singular surface, $x_0 \in X$, $p_2 : X \times X \rightarrow X$ the second projection, and $\Sigma_1$ and $\Sigma_2$ the sections $\{x_0\} \times X$ and $\Delta$ the diagonal. Let $I$ be the sheaf of ideals defining $\Sigma_1 \cup \Sigma_2$. Blow up $X \times X$ with respect to the sheaf of ideals $I$, to obtain $Y$. Denote the composite $Y \xrightarrow{\sigma} X \times X \xrightarrow{p_2} X$ by $f$. Then $Y$ non-singular outside of $\sigma^{-1}(x_0, x_0)$ and $f$ is of maximal rank outside $\sigma^{-1}(x_0, x_0)$. If we can show that (i) $Y$ is
non-singular, and (ii) \( \sigma^{-1}(x_0, x_0) \) is of dimension 2, it would follow that \( f^{-1}(x_0) \) has at least two components, and hence \( f \) cannot be regular all along \( f^{-1}(x_0) \).

To check these statements, we might as well blow up \( \mathbb{C}^4 \) with respect to the sheaf of ideals defined by \( \{ z_1 = z_2 = 0 \} \cup \{ z_3 = z_4 = 0 \} \) i.e. with respect to the sheaf of ideals generated by \( \{ z_1 z_3, z_1 z_4, z_2 z_3, z_2 z_4 \} \). The resulting space is covered by four open subsets, all of which are isomorphic, a typical one being the affine algebraic variety with co-ordinate ring

\[
\mathbb{C} \left[ \frac{z_1, z_2, z_3, z_4, z_2 z_4, z_2}{z_3, z_1 z_3} \right] = \mathbb{C} \left[ \frac{z_1, z_3, z_4, z_2}{z_3, z_1} \right]
\]

which is isomorphic to \( \mathbb{C}^4 \). The intersection of this open set with the fibre over the origin is given by \( z_1 = z_3 = 0 \), hence is 2-dimensional.

A topological characterisation of the affine plane as an algebraic variety

By C.P. Ramanujam*

1 Statement of results

This investigation arose from an attempt to answer the following question, raised by M. P. Murthy: If $X$ is an affine algebraic variety over a field $k$ such that $X \times A^1 \approx A^3$, where $A^n$ denotes the affine $n$-space over $k$, is $X$ isomorphic to $A^2$? It was hoped that when $k = \mathbb{C}$, just the hypothesis that $X$ is a non-singular, affine, rational and contractible surface would imply that $X \approx \mathbb{C}^2$. This, however, is not true as we show by a counter-example. We are unable to decide if the variety $Y$ of this counter-example also satisfies the condition $Y \times \mathbb{C} \approx \mathbb{C}^3$.

On the other hand, we do prove the following positive result.

**Theorem.** Let $X$ be a non-singular complex algebraic surface which is contractible AND simply connected at infinity. Then $X$ is isomorphic to the affine two-space as an algebraic variety.

The idea of the proof is to embed $X$ as a Zariski open subset of a complete non-singular surface such that the complement is a union of non-singular curves with normal crossings, and to use the contractibility and simple-connectedness at infinity of $X$ to work out the geometric

---

*This work was done when the author was at the Tata Institute of Fundamental Research.

1 Examples of compact 4-manifolds with boundary which are contractible and whose boundary is a homology 3-sphere but not a homotopy sphere have been given by several authors (Mazur, Poinereau, ——). Our counter-example also provides another such.
configuration of these curves. We prove that after suitable transformations, we are reduced to the case where the complement consists of a single non-singular curve, from which it follows easily that the compactification is the projective plane and the curve a line.

We shall first prove the theorem, and then proceed to give the counterexample. The methods of the proof of the theorem are analogous to those of Mumford [2].

2 Proof of the theorem

Let $X$ be as in the statement of the theorem. By the Nagata compactification theorem [3] and the theorem of resolution of singularities of an algebraic surface [1], we may assume $X$ embedded as a Zariski open subset of a complete non-singular (hence projective, see [4]) surface $\bar{X}$, such that if $\bar{X} - X = Y$ and $Y_i (1 \leq i \leq n)$ are the components of $Y$, each $Y_i$ is a complete non-singular curve, and we have the following further conditions:

(i) For two distinct indices $i, j$, either $Y_i \cap Y_j = \emptyset$ or $Y_i \cap Y_j$ consists of a single point where $Y_i$ and $Y_j$ meet transversally.

(ii) For three distinct indices $i, j, k$, $Y_i \cap Y_j \cap Y_k = \emptyset$.

The contractibility of $X$ implies some further conditions. In fact, by Poincaré duality on $X$, we get

$$H^i(\bar{X}, Y) \approx H^i_c(X) \approx H_{4-i}(X) \approx \begin{cases} 0 & \text{if } i < 4 \\ \mathbb{Z} & \text{if } i = 4, \end{cases}$$

so that by the cohomology exact sequence, we have isomorphisms

$$H^i(\bar{X}) \approx H^i(Y), \quad 0 \leq i \leq 3.$$ 

Hence $Y$ is connected, $H^2(\bar{X}) \to H^2(Y)$ is an isomorphism and $H^3(\bar{X}) = 0$. By duality, $H_1(\bar{X}) = 0$, hence also $H^1(Y) = 0$. From this, we deduce the following three conditions:

2 All homologies and cohomologies have integral coefficients, unless otherwise indicated. Cohomology with compact supports is denoted by $H^*_c$. 
(iii) Any two components \( Y_i, Y_j \) can be joined by a chain \( Y_i = Y_{i_1}, Y_{i_2}, \ldots, Y_{i_p} = Y_j \) such that \( Y_{i_k} \cap Y_{i_{k+1}} \neq \emptyset, 1 \leq k \leq p - 1 \).

(iv) There is no chain of components \( Y_{i_1}, \ldots, Y_{i_p} (p \leq 3) \) such that \( Y_{i_k} \cap Y_{i_{k+1}} \neq \emptyset, 1 \leq k \leq p - 1 \), and \( Y_{i_p} \cap Y_{i_1} \neq \emptyset \).

(v) Each \( Y_i \) is isomorphic to the complex projective line \( P^1 \).

In fact (iii) is just the connectedness of \( Y \). As for (v), let \( Y' \) be the union of all the connected components of \( Y \) excepting \( Y_i \). Since \( Y_i \cap Y' \) is a finite set of points, the Mayer-Vietoris sequence gives us that \( H^1(Y') \oplus H^1(Y_i) = 0 \), which implies (v). Next suppose there is a chain of components satisfying the conditions of (iv). Let \( Y' \) be the union of the components of the chain, and \( Y'' \) the union of \( Y_{i_1}, \ldots, Y_{i_{p-1}} \). Then \( Y'' \) is connected and \( Y'' \cap Y_{i_p} \) consists of at least two points, and it follows from the Mayer-Vietoris sequence

\[ 0 \to Z = H^0(Y') \to Z^2 \approx H^0(Y'') \oplus H^0(Y_{i_p}) \to Z'' \approx H^0(Y'' \cap Y_{i_p}) \to H^1(Y') \]

with \( \nu \geq 2 \) that \( H^1(Y') \neq 0 \). If \( Y''' \) is the union of the components of \( Y \) not belonging to the chain, the exact sequence

\[ 0 = H^1(Y) \to H^1(Y') \oplus H^1(Y''') \to H^2(Y' \cap Y''') = 0 \]

leads to a contradiction. Thus, (i)-(v) are established. We may also assume the further condition:

(vi) If some \( Y_i \) has self-intersection number \(-1\), it meets at least three other \( Y_j (j \neq i) \).

In fact, suppose \( (Y_i^2) = -1 \) and \( Y_i \) meet at most two other \( Y_j \). Then we can contract \( Y_i \) to obtain a non-singular complete surface \( \tilde{X}' \) such that \( X \) is isomorphic to an open subset \( X' \) of \( \tilde{X}' \), and \( Y' = \tilde{X}' - X' \) satisfies (i)-(v). If this does not suffice, we repeat the above process, till (vi) is satisfied.

Now \( H^3(\tilde{X}) = 0 \) implies \( H_2(\tilde{X}) \) is torsion-free, so that \( H_2(Y) \to H_2(\tilde{X}) \) is an isomorphism. Since \( H_2(Y) \) is freely generated by the
fundamental classes of its components \( Y_i (1 \leq i \leq n) \), we see that \( H^2(\bar{X}) \) is freely generated by the cohomology classes associated to the divisors \( Y_1, \ldots, Y_n \). Hence, with the usual notations,

\[
H^2(\bar{X}, C) \approx H^1(\bar{X}, \Omega^1)
\]

and \( H^2(\bar{X}, \mathcal{O}) = H^0(\bar{X}, \Omega^2) = 0 \). Since further \( H^1(\bar{X}, C) = 0 \), \( H^1(\bar{X}, \mathcal{O}) = 0 \) and \( \chi(\mathcal{O}_{\bar{X}}) = 1 \).

Now, denote by \( L = L(Y) \) the vector space \( \sum_i^n \mathbb{R} Y_i \) over \( \mathbb{R} \) with basis \( Y_i \), endowed with the quadratic form given by the intersection number extended by linearity. By the Hodge index theorem, we have

(vii) If \( W \) is any subspace of \( L \) on which the intersection form is positive semi-definite, \( \dim W \leq 1 \).

Now, consider any non-singular complete surface \( V \) and a Zariski-closed subset \( F \) of \( V \) of codimension one with irreducible components \( F_1, \ldots, F_n \) satisfying conditions (i)-(vii) (with \( Y, Y_i \) replaced by \( F, F_i \)). To such a pair \( (V, F) \), we attach a graph \( \Gamma = \Gamma(V, F) \) and weights which are integers to each of the vertices of \( \Gamma \) as follows. We take the vertices to be in one-one correspondence with the components \( F_i \) of \( F \), and link two vertices if and only if the corresponding components meet. The self-intersection number of a component is the weight of the corresponding vertex. This graph is a tree, that is, is connected and contains no loops, by (ii) and (iv).

Let \( \{P_\alpha\}(\alpha = 1, \ldots, \ell) \) be the various points of intersection of distinct components of \( F \). We can choose disjoint closed neighborhoods \( \bar{U}_\alpha \) of \( P_\alpha \) and holomorphic co-ordinate systems \( z_\alpha = (z_1^\alpha, z_2^\alpha) \) valid in a neighborhood of \( \bar{U}_\alpha \) such that:

(a) \( z_\alpha \) maps \( \bar{U}_\alpha \) homeomorphically onto the polycylinder \( \{z = (z_1^1, z_2^1) \in C^2 | |z_i| \leq 1 \} \).

(b) If \( F_i \) and \( F_j \) are the two components of \( F \) through \( P_\alpha \), no other
A topological characterisation of the affine plane as an algebraic variety

component of $F$ meets $\bar{U}_\alpha$ and $F_i \cap \bar{U}_\alpha$ and $F_j \cap \bar{U}_\alpha$ respectively are defined by the equations $z^{1}_\alpha = 0, z^{2}_\alpha = 0$ in $\bar{U}_\alpha$.

Choose a Riemannian metric $ds^2$ on $V$ such that in a neighborhood of $\bar{U}_\alpha$, $ds^2 = |dz^{1}_\alpha|^2 + |dz^{2}_\alpha|^2$. Then there is an $\epsilon > 0$ with $2\epsilon < 1$ such that: (a) the exponential map maps the open subset of the tangent bundle of $V$ consisting of tangent vectors of length $< 2\epsilon$ diffeomorphically onto an open neighborhood of the diagonal in $V \times V$, (b) the image of the $2\epsilon$-ball in the tangent space at any point of $V$ by the exponential map is a convex open neighborhood of that point, and (c) if $i \neq j$, $d(F_i - \bigcup \bar{U}_\alpha, F_j - \bigcup \bar{U}_\alpha) > 2\epsilon$. Denote by $\bar{V}_\delta = \bar{V}_\delta(F)$ the set of points in $V$ whose distance from $F$ is $\leq \delta$, by $S_\delta = S_\delta(F)$ the set of points whose distance from $F$ equals $\delta$ and set $V_\delta(F) = V_\delta = \bar{V}_\delta - S_\delta$. Then for $\delta < \epsilon$, $S_\delta$ is the boundary and $V_\delta$ the interior of $\bar{V}_\delta$ in $V$. From now on, $\delta$ always satisfies $0 < \delta < \epsilon$. We denote by $\bar{V}_\delta, S_\delta, i$, and $V_\delta$ the constructs corresponding to $\bar{V}_\delta, S_\delta, i$, and $V_\delta$ for $F_i$ instead of $F$. Then $\bar{V}_\delta = \bigcup_i \bar{V}_\delta$ and $V_\delta = \bigcup_i V_\delta$. The closed ball bundle $B_\delta$ of radius $\delta$ in the normal bundle of $F_i$ in $V$ is homeomorphic to $\bar{V}_\delta$ by the exponential map $\exp_i : B_\delta \rightarrow \bar{V}_\delta$. We denote the inverse of this homeomorphism by $\log_i$. Then $\log_i$ carries $S_\delta$ onto the circle bundle (of radius $\delta$) associated to the normal bundle of $F_i$.

**Lemma 1.** There is a homeomorphism

$$S_\delta \times (0, 1] \xrightarrow{\varphi} \bar{V}_\delta - F$$

such that $\varphi(x, 1) = x$ and $\varphi(S_\delta \times (0, \delta')) \cup F$ form a fundamental system of neighborhoods of $F$ on $V$. Further, $F$ is a strong deformation retract of $\bar{V}_\delta(F)$.

**Proof.** A point $x$ of $S$ at a distance $> \epsilon$ from any $P_\alpha$ lies on a unique $S_{\delta i}$. We then define for $0 < t \leq 1$,

$$\varphi(x, t) = \exp_i(t \log_i x).$$
Define $\varphi$ on each $(S_\delta \cap \bar{U}_\alpha) \times (0, 1]$ in terms of the co-ordinates $z_\alpha$ by

$$
\varphi(z_\alpha, t) = \begin{cases} 
(tz^1_\alpha, z^2_\alpha) & \text{if } |z^2_\alpha| \geq \epsilon \\
(z^1_\alpha, tz^2_\alpha) & \text{if } |z^1_\alpha| \geq \epsilon \\
(tz^1_\alpha, \left(t + (1 - t) \frac{|z^2_\alpha| - \delta}{\epsilon - \delta}\right)z^2_\alpha) & \text{if } \epsilon > |z^2_\alpha| \geq \delta \\
\left(t + (1 - t) \frac{|z^1_\alpha| - \delta}{\epsilon - \delta}\right)z^1_\alpha, tz^2_\alpha) & \text{if } \epsilon > |z^1_\alpha| \geq \delta.
\end{cases}
$$

![Fig. 1](image)

It is easily checked that $\varphi$ is well-defined on $S_\delta \times (0, 1]$ and satisfies the conditions of the lemma.

**Corollary.** The fundamental group at $\infty$ of $U = V - F$ is isomorphic to the fundamental group of $S_\delta$ for some (or any) $\delta < \epsilon$.

We will now examine how $S_\delta$ is built up from the $S_\delta_i(1 \leq i \leq n)$ or, what is the same, from the circle bundles $\Sigma_i$ associated with the normal bundles, considered as complex line bundles, of $F_i$ in $V$. For each $i$, we take the unique oriented circle bundle $\Sigma_i$ over $F_i \approx S^2$ of degree equal to the self-intersection number of $F_i$. If $F_i$ and $F_j$ intersect at a point

---

3We denote by $S^n$ the $n$-sphere, by $D^n$ the closed $n$-disc. For a subset $Y$ of a topological space $X$, we denote by $\mathring{Y}$, $\bar{Y}$ and $\partial Y$ the interior, closure and boundary, respectively, of $Y$ in $X$. 
A topological characterisation of the affine plane as an algebraic variety

Pα, let $D^2, D^2$ be closed discs of radius $\delta$ on $F_i$ and $F_j$, respectively. Denote by $\pi_i$ the projection $\sum_j \to F_i$. We have orientation-preserving trivialisations over the base $\pi^{-1}_i(D^2) \approx D^2 \times S^1, \pi^{-1}_j(D^2) \approx D^2 \times S^1$. We set $\sum'_i = \sum_i - (\pi^{-1}_i(D^2))^\circ$, and $\sum'_j = \sum_j - (\pi^{-1}_j(D^2))^\circ$, so that these are manifolds with boundaries $D^2 \times S^1, D^2 \times S^1$. We then identify $D^2 \times S^1$ and $D^2 \times S^1$ by a homeomorphism carrying $\partial D^2 \times \{x\}$ onto $\{y\} \times S^1$ (any $x, some y$ depending on $x$) and $\{x\} \times S^1$ onto $\partial D^2 \times \{y\}$ (any $x, some y$), preserving orientations. If we perform this operation for all the points of intersection of different components of $F$, we end up with $S_\delta$.

Thus, we see that $S_\delta$ is determined topologically by the following data: the number of components of $F$, the pairs among them which intersect, and their self-intersection numbers; in other words, the weighted graph associated with $F$.

Note that to any subsystem $G = \{G_1, G_2, \ldots, G_m\}$ of curves of $F = \{F_1, \ldots, F_n\}$, there corresponds a sub-graph $\Gamma'$ of $\Gamma$ such that two vertices of $\Gamma'$ are linked in $\Gamma'$ if and only if they are linked in $\Gamma$, and conversely, to any such sub-graph $\Gamma'$, there corresponds a sub-system of curves of $F$.

We introduce some definitions. Let $\Gamma$ be any connected graph, and $f$ a vertex of $\Gamma$. The connected components of the graph obtained by removing $f$ from the vertices of $\Gamma$ and deleting the links at $f$ are called the branches of $\Gamma$ at $f$. We say that $f$ is a branch point if the number of branches at $f$ is at least three. Now suppose $\Gamma$ is a graph with weights $\{w_e\}$ which are real numbers attached to the vertices $\{e\}$ of $\Gamma$. On the real vector space $L(\Gamma)$ with the vertices of $\Gamma$ as basis, we introduce a symmetric bilinear form $Q = Q(\Gamma)$ by defining

$$Q(e, e) = w_e$$

for any vertex $e$ of $\Gamma$,

$$Q(e, f) = \begin{cases} 
1 & \text{if } e \text{ and } f \text{ are distinct vertices linked in } \Gamma \\
0 & \text{if } e \text{ and } f \text{ are distinct vertices not linked in } \Gamma.
\end{cases}$$

Note that when $\Gamma$ is the weighted graph arising from a pair $(V, F)$ as above, $Q$ is nothing but the intersection form.

**Lemma 2.** Let $\Gamma$ be a graph with real weights $\{w_e\}$ attached to the vertices $\{e\}$ of $\Gamma$. Let $e, e'$ be two vertices of $\Gamma$ such that there is a unique
link $e\bar{e}'$ through $e$ in $\Gamma$. Suppose $w_e \neq 0$. Let $\Gamma'$ be the graph with the same vertices as $\Gamma$, but with the link $e\bar{e}'$ omitted from the links of $\Gamma$. Define weights $\{w'_f\}$ on the vertices $\{f\}$ of $\Gamma'$ by

$$w'_f = w_f \text{ if } f \neq e',$$

$$w'_e = w_{e'} - w_e^{-1}.$$  

Then the quadratic forms $Q(\Gamma)$ and $Q(\Gamma')$ are equivalent by a unimodular linear transformation. In particular, they have the same discriminant (with respect to the basis consisting of the vertices of $\Gamma$).

**Proof.** Express $Q(\Gamma)$ in terms of the basis of $L(\Gamma)$ given by $e, e' - w_e^{-1}e, f (f \neq e, e')$. □

**Corollary.** The determinant of the following graph with real weights $w_i$

$$\begin{array}{cccc}
  \circ & \circ & \cdots & \circ \\
  w_1 & w_2 & \cdots & w_k
\end{array} \quad (k \geq 1)$$

satisfying $w_1 < -1, w_i \leq -2$ for $i > 1$, is greater than one in absolute value.

**Proof.** Successive applications of the lemma, starting from the left, show that the discriminant equals $\prod_{1}^{k} q_i$, where $q_1 = w_1, q_{i+1} = w_{i+1} - q_i^{-1}$, Since $q_i < -1$, the result follows.

We shall denote the discriminant of $Q(\Gamma)$ by $d(\Gamma)$ and we shall write $d(F)$ for $d(\Gamma(Y, F))$. □

81 **Lemma 3.** Let $(V, F)$ be a pair satisfying conditions (i)-(vii). Then $d(F) \neq 0$ if and only if $H_1(S_\delta(F))$ is finite for small $\delta$, and in that case, $d(F)$ equals the order of $H_1(S_\delta(F))$.

**Proof.** We have the following commutative diagram
Here, $P_1, P_2$ are the isomorphisms of Poincaré duality theory, obtained by forming cap products with the fundamental classes of $V_\delta(F)$ (in the homology group of locally finite chains) and $V$, respectively, and $\alpha$ and $\beta$ are isomorphisms since $F \hookrightarrow V_\delta(F) \hookrightarrow \overline{V}_\delta(F)$ are homotopy equivalences. It follows that the composite map $H_2(F) \to H_2(F)$ obtained by following the upper row is that given by the intersection product $H_2(F) \times H_2(F) \to \mathbb{Z}$. Hence, $d(F) \neq 0$ if and only if this pairing is non-degenerate over $\mathbb{Q}$, and in this case $d(F)$ equals the order of the cokernel of $H_2(F) \to H_2(F)$. Now

$H^3(\overline{V}_\delta(F), S_\delta(F)) \approx H^1_c(V_\delta(F)) \approx H_1(V_\delta(F)) \approx H_1(F) = 0$,

so that the sequence

$$H^2(\overline{V}_\delta(F), S_\delta(F)) \to H^2(\overline{V}_\delta(F)) \to H^2(S_\delta(F)) \to 0$$

is exact. Further, by Poincaré duality on $S_\delta(F), H^2(S_\delta(F)) \approx H_1(S_\delta(F))$. This proves the lemma. □

Now, let $(V, F)$ satisfy conditions (i)-(vii) and let $\Gamma$ be its graph. For any connected subgraph $\Gamma'$ of $\Gamma$ such that two vertices of $\Gamma'$ are linked in $\Gamma'$ if and only if they are linked in $\Gamma$, let $F''$ denote the corresponding subsystem of curves of $F$. We shall denote by $\pi(\Gamma')$ the fundamental group $\pi_1(S_\delta(F'))$ for small $\delta$. Note that this is the fundamental group at infinity of $V - F'$. In particular, if $(W, G)$ is another pair satisfying (i)-(vii) such that $V - F$ and $W - G$ are isomorphic varieties, $\pi_1(S_\delta(F)) \approx \pi_1(S_\delta(G))$.

**Lemma 4 (Mumford).** Let $(V, F)$ satisfy (i)-(vii), and let $\Gamma$ be its graph. Let $e$ be a vertex of $\Gamma$ and $\Gamma_1, \ldots, \Gamma_p$ the branches at $e$. If $\pi(\Gamma) = (e)$, there are at most two branches $\Gamma_i$ such that $\pi(\Gamma_i) \neq (e)$.

**Proof.** Let $G_i$ be the system of curves corresponding to $\Gamma_i$, and $G$ the component of $F$ corresponding to $e$. Then $S_\delta(F)$ is obtained as follows. From each $S_\delta(G_i)$, one removes an open solid torus $(D^2_i \times S^1)$. Let $\pi : \Sigma(G) \to G$ be the oriented circle bundle over $G$ of degree equal
to the self-intersection number of $G$. Then one removes from $\Sigma(G)$ certain open solid tori of the form $\pi^{-1}(D_i^2)^\circ$, $D_i^2$ being disjoint discs on $G$. Choose trivialisation of $\Sigma(G)$ over the $D_i^2$ preserving orientation: $\pi^{-1}(D_i^2) \approx D_i^2 \times S^1$. Now one identifies $\partial D_i^2 \times S^1$ and $\lambda_i^{-1}(\partial D_i^2 \times S^1)$ by a homeomorphism $\varphi_i$ such that $\lambda_i \circ \varphi_i$ takes circles of the form $\partial D_i^2 \times \{x\}$ onto circles of the form $\{y\} \times S^1$.

Choose an open subset $U$ of $G$ containing all the $D_i'$ with a homeomorphism $U \approx R^2$ taking the $D_i$ onto discs in $R^2$ with centers on the unit circle and small radius, such that the centers of $D_1^2, D_2^2, \ldots$ occur in cyclic order on the unit circle (see Fig. 2). Join the origin $O$ of $R^2$ to points $x_i$ of $\partial D_i^2$ by straight lines $l_i$. Since the fibration $\pi$ restricted to $U$ is trivial, we can choose a base point

83 $O'$ in $\Sigma(G) - \bigcup i \pi^{-1}(D_i^2)$, curves $l_i'$ lifting $l_i$ leading from $O'$ to a point $x_i'$.
lying over \( x_i \) and loops \( \gamma'_i \) at \( x'_i \) whose projection \( \pi(\gamma'_i) \) is the loop \( \partial D_i^2 \) oriented positively at \( x_i \). Finally let \( \delta_i \) be the loop at \( x'_i \) describing the fiber \( \pi^{-1}(x_i) \approx S^1 \) once positively.

The fundamental group \( H \) of \( \sum(G) - \bigcup_i \pi^{-1}(D_i^2)^\circ \) is generated by \( c_i = l'_i \gamma'_i l_i^{-1}, \quad d_i = l'_i \delta_i l_i^{-1} \) with the relations \( d_1 = d_2 = \ldots = d_p(= d, \text{ say}), \quad c_j d_j c_i^{-1} d_j^{-1} = e \) and \( c_1 c_2 \ldots c_p = d^r \) for some \( r \in \mathbb{Z} \). Let \( G_i' \) be the fundamental group of \( S_\delta(G_i) - (D_i^2 \times S^1)^\circ \) based at the point \( y_i \) corresponding to the point \( x'_i \) on \( \pi^{-1}(\partial D_i^2) \). By van-Kampen’s theorem, \( \pi_1(S_\delta(G_i)) = G_i'' \) is the quotient of \( G_i' \) by the normal subgroup generated by the loop \( \partial D_i^2 \times x_i \) (for some point \( x_i \in S^1 \)) through \( y_i \). Again by van-Kampen’s theorem, the fundamental group \( \pi(\Gamma) \) of \( S_\delta(F) \) is the quotient of the free product

\[
G_1' \ast G_2' \ast \ldots \ast G_p' \ast H
\]

by the normal subgroup generated by \( d_i(\partial D_i^2 \times x_i)^{-1}(1 \leq i \leq p) \) and \( c_i \xi_i'^{-1} \) for some \( \xi_i' \in G_i' \). On dividing each \( G_i \) by \( \partial D_i^2 \times x_i \) and \( H \) by the (central) subgroup generated by \( d \), we see that \( \pi(\Gamma) \) has as quotient the group

\[
G_1'' \ast G_2'' \ast \ldots \ast G_p'' / \{ \xi_1 \ldots \xi_p \}
\]

where \( \xi_i \) are the images of \( \xi_i' \) in \( G_i'' \), and for any \( \eta \), we denote by \( \{ \eta \} \) the normal subgroup generated by \( \eta \).

Now, if there are three indices \( i \) for which \( G_i'' \) is non-trivial, \( \pi(\Gamma) \) has as quotient a group of the form

\[
H_1 \ast H_2 \ast H_3 / \{ \eta_1 \eta_2 \eta_3 \}
\]

where \( H_i \) are non-trivial groups and \( \eta_i \in H_i \). Since \( \pi_1(\Gamma) = \{ e \} \) by the assumption, the above group should also be trivial. But by Mumford’s lemma \([2]\) this group is non-trivial, which is a contradiction. \( \square \)

**Lemma 5.** Let \((V, F)\) be a pair satisfying (i)-(vii) with graph \( \Gamma \). Suppose there is a subgraph \( \Gamma' \) of the form

\[
\begin{array}{cccccccc}
\bullet & - & - & - & - & - & - & - & \bullet \\
w_1 & w_2 & & & & & & w_k
\end{array}
\]

\((k \geq 1)\)
(where the $w_i$ denote the weights) with $\pi(\Gamma') = (e)$ such that no vertex of $\Gamma'$ is a branch point of $\Gamma$. Then there is a pair $(W, G)$ satisfying (i)-(v) and (vii) such that the following conditions hold:

(i) There is an isomorphism of varieties $V - F \cong W - G$;

(ii) The graph of $(W, G)$ is obtained from the graph $\Gamma$ of $(V, F)$ by pinching $\Gamma'$ to a single vertex in $\Gamma$ and giving it a weight +1. (The weights at vertices not in $\Gamma'$ may get changed.)

Proof. We proceed by induction on $k$. When $k = 1$, $w_1 = \pm 1$ since $\pi(\Gamma') = (e)$, and $w_1 = -1$ is ruled out by assumption (vi). Assume that the result holds when the number of vertices in $\Gamma'$ is $< k$. Now, all the weights $w_i$ cannot be $< 0$, since they would then be $\leq -2$ and $|d(\Gamma')| > 1$. If there are at least three non-negative weights, some two vertices which are not linked must have non-negative weights, and there is a two dimensional subspace of $L(\Gamma')$ on which $Q(\Gamma')$ is positive semi-definite. Hence the number of non-negative weights is either one or two, and if it is two, the corresponding vertices must be linked and one of the weights must be 0.

Suppose the number of non-negative weights is one, say $w_{i_0} \geq 0$ and $w_i \leq -2$ for $i \neq i_0$. By Lemma [2] the discriminant $d(\Gamma')$ equals

$$d(\Gamma') = q_1 \cdot q_2 \cdots q_{i_0-1} \cdot r_1 \cdot r_2 \cdots r_{k-i_0} \cdot (w_{i_0} - q_{i_0-1}^{-1} - r_{k-i_0}^{-1})$$

where $q_1 = w_1$, $q_{i+1} = w_{i+1} - q_i^{-1}$ for $i \geq 1$, $r_1 = w_k$, $r_{i-1} = w_{k-i+2} - r_i^{-1}$ for $i \leq k$. (Omit the $q$’s if $i_0 = 0$ and the $r$’s if $i_0 = k$). Thus, $q_i, r_i < -1$ and if $w_{i_0} \geq 1$, $|d(\Gamma')| > 1$. Thus, $w_{i_0} = 0$, and

$$d(\Gamma') = -q_1 \cdots q_{i_0-2} \cdot r_1 \cdots r_{k-i_0} - q_1 \cdots q_{i_0-1} \cdot r_1 \cdots r_{k-i_0-1}$$

if $2 \leq i_0 \leq k - 1$. This again leads to $|d(\Gamma')| > 1$. Thus, $i_0$ must be 1 or $k$, and we may assume $i_0 = 1$ by symmetry. Again, one sees that necessarily $k = 2$, so that $\Gamma'$ has to be the weighted graph

$$\begin{array}{c}
0 \quad \longrightarrow \quad -n \\
\end{array}$$

$n \in \mathbb{Z}, \quad n \geq 2.$
Let $L$ be the line corresponding to the first vertex. If this vertex is linked to a vertex $f$ of $\Gamma$ not in $\Gamma'$, let $L'$ be the line corresponding to $f$. Choose an arbitrary point $P$ on $L$ if there is no such $f$, and choose $P$ to be the point of intersection of $L$ and $L'$ if there is an $f$. Blow up $P$, and contract the proper transform of $L$. Repeat this procedure $(n-1)$ times, till we get a pair $(W', G')$, satisfying conditions (i)-(v) and (vii) such that $V - F \approx W' - G'$, and the graph of $(W', G')$ is isomorphic to $\Gamma$. Further, the weights of $\Gamma'$ are 0 and $-1$ respectively. Contract the line corresponding to the weight $-1$, to get $(W, G)$ as required.

Next suppose there are two non-negative weights in $\Gamma'$. By condition (vii), these must be linked and one of them must be 0. Thus, $\Gamma'$ looks like

\[ p_1 \quad p_2 \quad \cdots \quad p_r \quad n \quad 0 \quad q_s \quad q_{s-1} \quad q_1 \]

with $r \geq 0$, $s \geq 0$, $n \geq 0$, $r + s + 2 = k$. Blow up the point of intersection of the lines corresponding to the vertices with weights $n$ and 0, and contract the proper transform of the line corresponding to the vertex of weight 0. Repeat this $n + 1$ times to get $(W', G')$ satisfying conditions (i)-(v) and (vii) with a graph isomorphic to the original graph but the weights changed as follows:

\[ p_1 \quad p_2 \quad \cdots \quad p_r \quad -1 \quad 0 \quad q_s + n + 1 \quad q_{s-1} \quad q_1 \]

Now shrink the line corresponding to the vertex with weight $-1$. We get a pair $(W'', G'')$ satisfying (i)-(v) and (vii). The graph of this pair is obtained from $\Gamma$ by pinching two adjacent vertices to one and replacing the weights $p_r$ and 0 by $p_r + 1$ and 1, respectively. Since $k$ is now decreased, the assertion of the lemma follows by induction hypothesis.

\[ \square \]

Remarks. (1) The pair $(W, G)$ obtained from the lemma need not necessarily satisfy (vi), since certain weights at vertices of $\Gamma$ not in $\Gamma'$ are also altered. However, the only weights which are altered are those at vertices directly linked to the first or last vertex of
Now, we can shrink suitable exceptional curves of the first kind successively to obtain a pair \((\bar{W}, \bar{G})\) which satisfies all the conditions (i)-(vii), with \(\bar{W} - \bar{G} \simeq V - F\). However, the graph of \((\bar{W}, \bar{G})\) is not describable in such a simple fashion as that of \((W, G)\), though we can make the following assertion. *The number of branch points of the graph of \((\bar{W}, \bar{G})\) is the same as that of \(\Gamma\).* In fact, if this were not so, we would necessarily have (a) the maximal linear subgraph \(\Gamma''\) of \(\Gamma\) containing \(\Gamma'\) but not any branch point of \(\Gamma\) must be linked to exactly one vertex of \(\Gamma\) so that it is a branch at a branch point of \(\Gamma\), and (b) the system of curves corresponding to \(\Gamma''\) must be collapsible to a single point on a non-singular surface. But now (b) implies that the restriction of the intersection form to the space spanned by the vertices of \(\Gamma''\) is negative definite. This is not so on \(\Gamma'\), as we have shown above.

(2) During the course of the proof, we have also established that there is no system of curves satisfying (i)-(vii) whose graph is linear, contains no non-negative weights, and has discriminant \(\pm 1\); and that the only systems satisfying (i)-(vii) with a linear graph of discriminant 1 in absolute value containing a unique vertex with non-negative weight are those with the graphs

\[
\begin{align*}
0 &- n, \quad n \in \mathbb{Z}, \quad n \geq 2 \quad \text{and} \quad 1 \\

\end{align*}
\]

**Lemma 6.** *On a complete non-singular surface \(V\) with \(H^1(V, \Theta_v) = 0\), there cannot exist a system of five lines \(L_i(1 \leq i \leq 5)\) satisfying conditions (i)-(v) whose weighted graph looks like*

\[
\begin{align*}
\begin{array}{c}
L_1 \\
L_2 \\
L_3 \\
L_4 \\
L_5
\end{array}
\end{align*}
\]

with \((L_3^2) = -1\) and \((L_5^2) \geq 0\).

**Proof.** Shrink \(L_3\) on \(V\) to a point on a non-singular surface \(V'\) and denote by \(L_i'(i \neq 3)\) the image of \(L_i\) in \(V'\). Then \(L_1', L_2'\) and \(L_4'\) meet at a
point $P$, and $L'_4$ and $L'_5$ meet transversally at a point $Q \neq P$. Since $H^1(V', \mathcal{O}_{V'}) = 0$ we have the exact sequence

$$0 \to C = H^0(V', \mathcal{O}_{V'}) \to H^0(V', \mathcal{O}_{V'}(L'_5)) \to H^0(L'_5, \mathcal{O}_{V'}(L'_5)|L'_5) \to 0.$$ 

Thus the complete linear system $|L'_5|$ cuts out on $L'_5$ the complete linear system of divisors of degree $n = (L'_5^2) \geq 0$. Hence $|L'_5|$ has no base points, and since $(L'_4 \cdot L'_5) = 1$, $|L'_5|$ cuts out the complete linear system of divisors of degree 1 on $L'_4$. Choose a divisors $D \in |L'_5|$ such that $D$ cuts out the point $P$ on $L'_4$. Since $(L'_5 \cdot L'_1) = (L'_5 \cdot L'_2) = 0$, $D$ must have $L'_1$ and $L'_2$ for components but not $L'_4$. But then,

$$(L'_5 \cdot L'_4) = (D \cdot L'_4) \geq ((L'_1 + L'_2) \cdot L'_4) \geq 2,$$

a contradiction. \hfill $\Box$

**Corollary.** With $V$ as in Lemma 6 there cannot exist a system of four lines $\bar{L}_i (1 \leq i \leq 4)$ satisfying (i)-(v) whose graph looks like

![Diagram](https://via.placeholder.com/150)

and $(L^2_3) = 0$, $(L^2_4) > 0$.

**Proof.** If we blow up the point of intersection of $L_3$ and $L_4$ on $V$, we are landed with a system of five lines as in Lemma 6.

Let us call a subgraph $\Gamma'$ of a graph $\Gamma$ *simple* if $\Gamma'$ is linear and no vertex of $\Gamma'$ is a branch point of $\Gamma$. We shall say that a branch point of $\Gamma$ is *extremal* if all but one of the branches at this point are simple. We say that a connected subgraph $\Gamma'$ of $\Gamma$ is *spherical* if $\pi(\Gamma') = (e)$.

The proof of the main theorem follows immediately from the following \hfill $\Box$

---

4This only means that if $F'$ is the system of curves corresponding to $\Gamma'$, $S_\delta(F)$ is a homotopy 3-sphere.
**Proposition.** There is no pair \((V, F)\) with \(H^1(V, \mathcal{O}_V) = 0\) satisfying (i)-(vii) such that \(\pi_1(S_\delta(F)) = (e)\) and the graph \(\Gamma\) not linear.

**Proof.** Suppose in fact that there is such a pair. By Lemma 5 and the succeeding remark (1), we may assume that any simple branch at any branch point which is spherical consists of a single vertex with weight 1. Let \(k \geq 1\) be the number of branch points of \(\Gamma\).

Suppose first that \(k = 1\), and let \(e\) be the branch point. Then the branches at \(e\) are all simple; if these are \(\geq 4\) in number, at least two of them must be spherical by Lemma 4 and hence consist of single vertices with weight 1. But this clearly contradicts (vii). Thus there are exactly three branches, and one of them is spherical, hence consists of a vertex of weight 1. The graph looks like

![Diagram](https://example.com/diagram.png)

where \(\Gamma_i\) are simple branches. By (vii), the weights of the vertices on \(\Gamma_i\) must be \(\leq -2\), and the weight \(w\) at \(e\) is \(\leq 0\). If \(w = 0\), we get a contradiction by the Corollary to Lemma 6. If \(w \leq -1\), use Lemma 2 to conclude that \(d(\Gamma)\) = the discriminant of the graph, the weights in this graph at vertices on \(\Gamma_i\) being the same as in the original one. Since \(w - 1 \leq -2\), we see that \(|d(\Gamma)| > 1\) by the Corollary to Lemma 2 and we get a contradiction by Lemma 3.

Hence suppose \(k > 1\), and that we have ruled out the possibility of a pair as in the proposition with fewer branch points. Let \(S\) denote the set of extremal branch points of \(\Gamma\). We assert that \(\text{Card}(S) \geq 2\). In fact, start from an arbitrary branch point \(e\) of \(\Gamma\). We assert that \(\text{Card}(S) \geq 2\). In fact, start from an arbitrary branch point \(e\) of \(\Gamma\). There is a branch at \(e\) containing a branch point of \(\Gamma\), since \(k \geq 2\), and there are at least two such branches at \(e\) if \(e\) is not extremal. Travel along one of these branches (without retracting one’s path) till one reaches a branch point \(f\). If \(f\) is not extremal, we can choose a branch at \(f\) not containing \(e\) but containing a branch point. Travel along this branch. Continuing in this
manner, we see that on every branch at $e$ which is not simple, there is an extremal branch point. This proves that $\text{Card}(S) \geq 2$.

Denote by $S'$ the subset of $S$ consisting of those vertices $e \in S$ such that every simple branch at $e$ carries only weights $< 0$ (hence $\leq -2$). Because of (vii), we have $\text{Card}(S') \geq \text{Card}(S) - 1 \geq 1$.

Let $e$ be an arbitrary element of $S'$. There must be exactly two simple branches at $e$, since otherwise there would exist a simple spherical branch at $e$ by Lemma 4 and this branch would consist of a single vertex with weight 1 by assumption, contradicting the fact that $e \in S'$. Let $\Gamma'$ be the non-simple spherical branch at $e$ and $f$ the point of this branch linked to $e$ in $\Gamma$. If $f$ is a branch point of $\Gamma'$, the system of curves corresponding to $\Gamma'$ would satisfy (i)-(vii) and $\Gamma'$ is spherical, which is impossible by the induction hypothesis. For the same reason, it cannot happen that $f$ is not a branch point of $\Gamma$. Thus $f$ is a branch point of $\Gamma$ with exactly three branches in $\Gamma$ at $f$.

We deal separately with the case $k = 2$. The graph looks like

```
l_1
 \ |
 l_2
 \ |
 e
 f
 \ |
 l_3
 l_4
```

where $e$ and $f$ are linked branch points and $l_i(1 \leq i \leq 4)$ are simple branches such that the weights on $l_1$, $l_2$ and one of $l_3$, $l_4$, say $l_3$, are negative. Let $\delta_i$ be the discriminants of $l_i$ and $\Delta_1$ and $\Delta_2$ the discriminants of $l_1$ and $l_2$ respectively. By taking the weights to be variables and applying Lemma 2 repeatedly to remove the links on the simple branches and the links connecting these branches to the branch points, one obtains the identity $\text{disc}(\Gamma) = \Delta_1 \Delta_2 - \delta_1 \delta_2 \delta_3 \delta_4$.

Since $l_4$ is spherical, $|\Delta_2| = 1$, and since the weights on $l_i(1 \leq i \leq 3)$ are $\leq -2$, $|\delta_i| > 1$ and hence $\geq 2$ by the Corollary to Lemma 2. If $\delta_4 = 0$, the quadratic form of $l_4$ is degenerate, and hence by (vii) should be negative semi-definite with null-space of dimension one. If this happens, there must be a non-negative weight in $l_4$ and this weight must then necessarily be 0. The corresponding vertex must belong to the null-space of the quadratic form. But then, this vertex cannot
be linked to any other vertex of \( l_4 \), so that \( l_4 \) should reduce to a single vertex with weight 0. But then, the graph \( l_1e l_2 \) cannot be spherical, since we would then have \( w_e = -1 \) by remark (2) following Lemma 5 in contradiction to Lemma 6. Suppose then that \( \delta_4 \neq 0 \), so that \( |\delta_4| \geq 1 \) and \( |\delta_2\delta_3\delta_4| \geq 8 \); since \( 1 = |d(\Gamma)| = |\Delta_1\Delta_2 - \delta_1\delta_2\delta_3\delta_4| \) and \( |\Delta_2| = 1 \), we must have \( |\Delta_1| \neq 1 \) and again \( l_1e l_2 \) cannot be spherical. Applying Lemma 4 to the branch point \( f \), we deduce that \( l_4 \) is spherical, hence reduces to a single vertex with weight 1. Because of (vii) we must have \( w_f \leq 0 \), and by the Corollary to Lemma 6 \( w_f \neq 0 \), so that \( w_f \leq -1 \). Using Lemma 2 the discriminant of \( l_3f l_4 \) equals that of \( l_3f \) with \( w_f \) replaced by \( w_f - 1 \), so that all the weights of the latter graph are \( \leq -2 \) and its discriminant exceeds 1 in absolute value, a contradiction.

Thus, we assume from now on that \( k \geq 3 \). Reverting to our old notations, we have seen that if \( e \in S' \), there are two simple branches at \( e \), and on the third spherical branch \( \Gamma' \), the point \( f \) linked to \( e \) is a branch point of \( \Gamma \) with three branches. Since \( \Gamma' \) has at least one branch point, if \( w_f \neq -1 \), the system of curves corresponding to \( \Gamma' \) satisfies conditions (i)-(vii) and \( \Gamma' \) is spherical, which is impossible by the induction hypothesis. Furthermore, \( \Gamma' \) satisfies conditions (i)-(v) and (vii), and (vi) can be ensured by successively contracting exceptional curves corresponding to non-branch points. Since \( \Gamma' \) is spherical, this implies that the above process of shrinking suitable exceptional curves should eliminate all branchings. As is easily seen, this implies in particular that one of the branches at \( f \) is simple with all weights less than 0, hence \( \leq -2 \). Thus, in the vicinity of a point \( e \in S' \), \( \Gamma \) looks like

\[
\begin{array}{c}
\vertex{e} \\
l_1 \quad l_2 \quad l_3 \\
\gamma
\end{array}
\]  

where the \( l_i \) are simple branches, all having weights \( \leq -2 \), \( w_f = -1 \), and \( \gamma \) is an arbitrary branch containing at least one branch point of \( \Gamma \).

Define \( S'' = \{ e \in S'|w_e = -1 \} \). Suppose \( S'' \neq \emptyset \); then the intersection form is 0 on \( e + f \). We assert that this implies that there is no
non-negative weight. In fact, if \( w_g \geq 0 \) for some \( g \), then by condition (vii), \( g \) must be linked to either \( e \) or \( f \). But this is again impossible by Lemma 6. In particular, we have \( S = S' \). Suppose on the other hand that \( e \in S' - S'' \). Then \( l_1 e l_2 \) cannot be spherical by the Corollary to Lemma 5 and the remarks following it. Thus, Lemma 4 applied to \( f \) gives us that \( \gamma \) is spherical. Since \( \gamma \) contains branch points of \( \Gamma \), we deduce as before that the point on \( \gamma \) linked to \( f \) is a branch point of \( \Gamma \) with exactly three branches.

Let us dispose of the case \( k = 3 \). Suppose first that \( S'' \neq \emptyset \) and \( e \in S'' \). Denote by \( g \) the third branch point besides \( e \) and \( f \). We know that all weights are \( < 0 \). Suppose \( g \) is not linked to \( f \) directly. We can then apply Lemma 4 to \( \Gamma \) at \( g \) to get a contradiction to our induction hypothesis. By the same token, there are exactly three branches at \( g \), two of them simple. Now, we know that \( \Gamma' \) is spherical. Apply Lemma 4 to \( \Gamma' \) at \( g \) to deduce that all the weights on \( l_3 \) equal \(-2\). Apply Lemma 4 to \( \Gamma \) at \( g \) to deduce that is spherical. Note that \( w_e = w_f = -1 \). Shrink the curves corresponding to vertices on the branch at \( e \) containing \( l_3 \), to get a linear spherical graph with all but one of the weights \( \leq -2 \) and a weight at a unique vertex which is not an end vertex \( \geq 0 \). This is impossible. Thus, \( S'' = \emptyset \), and in this case, by what we have seen earlier, the graph looks like

with all the weights on \( l_1, l_2 \) and \( l_3 \) and one of \( l_4 \) or \( l_5 \), say \( l_4 \), negative, and \( w_f = -1, w_e \neq -1 \). Now, \( l_5 \) cannot be spherical since it would then consist of a single vertex of weight 1 by assumption, contradicting
Lemma 6. Applying Lemma 4 at $g$, we see that

is spherical. Thus the horizontal branch of this graph at $e$ should be collapsible, and all the weights on $l_3$ should be equal to $-2$. Now, both the graphs

are spherical, hence have discriminants $= \pm 1$. But the discriminant of the second graph equals that of the first graph with $w_g$ replaced by $w_g + r$ where $r$ is an integer $\geq 2$. But clearly the discriminant of the first graph is a linear function of $w_g$, the coefficient of $w_g$ being $\delta_4\delta_5$, where $\delta_i$ is the discriminant of $l_i$. Now, $\delta_i$ are integers, $|\delta_4| \geq 2$, so that the above can happen only if $\delta_5 = 0$. But then the quadratic form of $l_5$ must be negative semi-definite with null-space of dimension one. Thus, at least one weight on $l_5$ is $\geq 0$, hence equal to 0. This vertex must therefore belong to the null-space, and must be orthogonal to all the vertices for the quadratic form. Thus, $l_5$ consists of a single vertex of weight 0, contradicting Lemma 6.

Hence $k = 3$ is impossible, and we assume from now on that $k \geq 4$. We look more closely at the branch $\gamma$ when $e \in S' - S''$. Since $\gamma$ is spherical and contains at least two branch points of $\Gamma$, one of which, say $g$, is linked to $f$, we deduce as before that $w_g = -1$ and one of the three branches at $g$ is simple with weights $\leq -2$. Thus, in the vicinity of $e$, $\Gamma$ looks like

![Diagram of graph with weights and branches](image)
Further, $\Gamma'$ spherical gives us that all the weight on $l_3$ should be $-2$. Again, a repetition of an earlier argument applied to the branch $\gamma$ tells us that there is a branch point of $\Gamma$ in $\gamma'$ linked to $g$ in $\Gamma$. But then, $\gamma$ being spherical implies that all the weights on $l_4$ equal $-2$.

Now, collapse all exceptional curves at non-branch points of $\Gamma'$, that is, collapse the branch $l_3f$ at $g$. We are left with the graph $\gamma$:

![Graph diagram]

except that the weight at $g$ is replaced by $w_g + r = r - 1$, $r$ an integer $\geq 2$. But this graph fulfills all the conditions (i)-(vii), contains a branch point and is spherical, which is impossible. Thus for $k \geq 4$, $S' - S'' = \emptyset$, $S' = S''$, and hence (since $\text{Card}(S') \geq 1$) $S = S' = S''$, $\text{Card}(S) \geq 2$. Choose two distinct vertices $e, e' \in S''$, and denote the objects corresponding to the objects $l_i, f, \gamma$ associated to $e'$ by the same symbols with a prime. Since $e + f$ and $e' + f'$ both have self-intersection 0, one of $e, f$ must either coincide with or be linked to one of $e', f'$. But $e$ is linked only to $f$ besides non-branch points and $e'$ only to $f'$ besides non-branch points. Thus, either $f = f'$ or $f$ and $f'$ are linked. If $f = f'$, looking at the structure of $\Gamma$ near $e$ and $e'$, we see that there can be only three branch points $e, f = f'$ and $e'$. Hence $f$ and $f'$ are linked, and $\Gamma$ looks like

![Graph diagram]

with all weights $< 0$, $w_e = w_{e'} = w_f = w_{f'} = -1$. Now, the fact that the non-simple branch at $e$ is spherical gives us (by our induction hypothesis) that all the weights on $l_3$ are equal to $-2$. Collapsing $l_3f$ on this branch by successively shrinking lines corresponding to non-branch vertices with weight $-1$ gives us that the graph
where the weight at \( f' \) is replaced by \( w_{f'} + r = r - 1, r \geq 2 \), is spherical. But this new graph satisfies all the conditions (i)-(vii) and contains a branch point. This is impossible.

Thus the Proposition is proved.

\[ \square \]

The theorem follows almost immediately. In fact, imbed \( X \) in \( \bar{X} \) such that \( \bar{X} - X = Y \) satisfies conditions (i)-(vii) as explained at the beginning of this section. By the Corollary to Lemma \[11\] and the Proposition \( \Gamma(Y) \) does not contain branch points, and is hence linear. By Lemma \[5\] we may assume that \( Y \approx \mathbb{P}^1 \) and has self-intersection 1. The exact sequence

\[ 0 \rightarrow C = H^0(\bar{X}, \mathcal{O}_{\bar{X}}) \rightarrow H^0(\bar{X}, \mathcal{O}_{\bar{X}}(Y)) \rightarrow H^0(Y, \mathcal{O}_{\bar{X}}(Y)|Y) \rightarrow H^1(\bar{X}, \mathcal{O}_{\bar{X}}) = 0 \]

shows that the complete linear system \( |Y| \) has no base points, and defines a morphism \( \varphi \) of degree 1 (since \( (Y^2) = 1 \)) into \( \mathbb{P}^2 \). Since the Neron-Severi group of \( \bar{X} \) is \( \mathbb{Z} \), \( \varphi \) cannot contract any curve, so that \( \varphi \) is an isomorphism. Hence \( X = \bar{X} - Y \approx \mathbb{P}^2 - \{ \text{line} \} = \mathbb{C}^2 \), proving the theorem.

### 3 The counter-example

Consider in the projective plane \( \mathbb{P}^2 \) a cubic curve \( C_1 \) with a cusp and a non-degenerate conic \( C_2 \) meeting \( C_1 \) at two distinct points \( P \) and \( Q \), which are simple on \( C_1 \) and different from the inflexion point of \( C_1 \), with intersection numbers 5 and 1 respectively. (That such a configuration exists, and in fact, \( C_1 \) and either \( P \) or \( Q \) can be chosen arbitrarily, is easily seen, for instance using the fact that \( C_1 - \{ \text{cusp} \} \) is an algebraic group isomorphic to the additive group of \( \mathbb{C} \), and a conic meets \( C_1 \) at simple points \( P_i (1 \leq i \leq 6) \), each point being repeated as many times as the intersection multiplicity, if and only if \( \sum_1^6 P_i = 0 \) for this group
law.) Blow up the point $Q$ to obtain a variety $F$ and let $C'_1$ be the proper transform of $C_i$. The variety $X = F - C'_1 - C'_2$ is our counter-example.

Put $C' = C'_1 \cup C'_2$, so that $C'$ is topologically the wedge of two 2-spheres, so that $H_1(C') = 0$ and $H_2(C')$ is the free abelian group on the classes defined by $C'_1$ and $C'_2$. Now, $F$ is simply-connected, and $H_2(F)$ is generated by the class $E$ of the exceptional curve and the class $H$ defined by the total transform of a line in $\mathbb{P}^2$. But in $H_2(F)$, we have the relations $C'_1 = 3H - E$, $C'_2 = 2H - E$. Further, $H_3(F) \approx H^1(F) = 0$. Thus $H_i(C) \rightarrow H_i(F)$ is an isomorphism for $0 \leq i \leq 3$, and $H_i(F, C) = 0$ for $0 \leq i \leq 3$. Thus we also have

$$H_i(X) = H^{4-i}(X) = H^{4-i}(F, C) = 0, \quad 1 \leq i \leq 4.$$ 

To show that $X$ is contractible, it suffices to show that $\pi_1(X)$ is abelian, since it would then follow that $\pi_1(X) = H_1(X) = (e)$.

Now $F$ is a projective line bundle over $\mathbb{P}^1$ whose fibers are the proper transforms of the lines in $\mathbb{P}^2$ through the point $Q$ in $F$. Since the intersection number of any fiber with $C'_2$ is 1, $C'_2$ is a section of this fibration $\pi : F \rightarrow \mathbb{P}^1$ and the restriction of $\pi$ to $F - C'_2$ is an affine line bundle over $\mathbb{P}^1$. If $P'$ is the inverse image of $P$, we may assume that $\pi(P)$ is the point at infinity. If $G = F - C'_2 - \pi^{-1}(\infty)$, $G$ is an affine line bundle over $\mathbb{P}^1 - (\infty) = C$. Since affine line bundles over $C$ are trivial, we have $G \approx C \times C$ such that the restriction of $\pi$ to $G$ identifies itself to the first projection of $C \times C$ onto $C$. Now, the proper transform of a line through $Q$ in $\mathbb{P}^2$ meets $C'_1$ in one point if and only if either the line passes through the singularity of $C_1$ or the line is tangent to $C_1$ at a point which is simple and distinct from $Q$. Now, it is easily seen that there is exactly one line through $Q$ tangent to $C_1$ at a simple point other than $Q$ and this point has to be distinct from $P$ or the inflexional point of $C_1$. Since $C'_1$ and $C'_2$ meet only at the point $P'$, $G \cap C'_1$ is proper over $C$, of degree 2, and exactly two fibers of the map $G \cap C_1 \rightarrow C$ reduce to a single point. Denoting the coordinates in $C \times C$ by $(z, w)$, we see that the equation of $C'_1$ in $C \times C$ has the form $w^2 + a(z)w - p(z) = 0, a, p \in C[z]$. Replacing $w$ by $w + \varphi(z)$ for a suitable polynomial $\varphi$, we may assume that the equation is $w^2 = p(z)$. Since exactly two fibers in $C'_1$ reduce to
a point, \( p(z) \) has exactly two zeros and after a linear change of \( z \) and \( w \) we may assume the equation of \( C'_1 \) in \( \mathbb{C} \times \mathbb{C} \) has the form

\[
w^2 = z^m(z - 1)^n, \quad m, n \geq 1.
\]

We may assume that the singularity of \( C'_1 \) lies over 0, and the the point over 1 in \( C'_1 \) is simple. This gives \( n = 1 \), and the fact that the singularity of \( C'_1 \) is an ordinary cusp (i.e., on blowing up the singular point, the proper transform of \( C_1 \) is non-singular and touches the exceptional curve exactly one point) gives us that \( m = 3 \). Thus, \( C'_1 \cap \mathbb{C} \times \mathbb{C} \) has the equation

\[
w^2 = z^3(z - 1).
\]

Now, \( \mathbb{C} \times \mathbb{C} - \{z(z - 1) = 0\} - C'_1 \) is a locally trivial fiber space over \( \mathbb{C} - \{0, 1\} \) with typical fiber the complex plane with two points removed. The homotopy exact sequence shows that \( \pi_1(\mathbb{C} \times \mathbb{C} - \{z(z - 1) = 0\} - C'_1) \) is generated by the fundamental group of the fiber and loops at the base points whose images by \( \pi \) are loops around 0 and 1 in \( \mathbb{C} - \{0, 1\} \). Choose the base point to be \( (1/2, M) = A \) with \( M \) sufficiently large. Further note that

\[
\pi_1(\mathbb{C} \times \mathbb{C} - \{z(z - 1) = 0\} - C'_1) \twoheadrightarrow \pi_1(\mathbb{C} \times \mathbb{C} - C_1)
\]

is surjective. We can choose loops at \( A \) lifting the loops at \( 1/2 \) in \( \mathbb{C} - \{0, 1\} \) around 0 and 1 with the \( w \)-co-ordinate constantly \( M \), and these loops can be contracted in \( \mathbb{C} \times \mathbb{C} - C'_1 \). Thus we see that \( \pi_1(\mathbb{C} \times \mathbb{C} - C'_1) \) is generated by the fundamental group of any fiber of \( \mathbb{C} \times \mathbb{C} - C'_1 \) over a \( \lambda \in \mathbb{C}, \lambda \neq 0, 1 \). Since the \( w \)-co-ordinates of the two points of \( C'_1 \) lying over a \( \lambda \) tend to 0 as \( \lambda \) tends to 1, if \( U \) is any connected neighborhood of \( (1, 0) \) in \( \mathbb{C} \times \mathbb{C} \), \( \pi_1(U - C'_1) \to \pi_1(\mathbb{C} \times \mathbb{C} - C'_1) \) is surjective. Now choose \( U \) such that there are co-ordinates \( (z', w') \) valid in \( U \) and mapping it on to the polycylinder \( \{(z', w')|z'| < 1, |w'| < 1\} \) such that \( C'_1 \cap U \) is mapped onto \( z' = 0 \). Then \( \pi_1(U - C'_1) \) is infinite cyclic. We have thus proved that \( X \) is contractible. Now, after successive blowings up of points on \( C'_1 \cup C'_2 \) and its inverse images, starting from \( F \), we get an embedding \( X \hookrightarrow \tilde{X} \) where \( \tilde{X} \) is a non-singular complete surface and the pair \( (\tilde{X}, \tilde{X} - X) \) satisfies conditions (i)-(vii) of § 2. The associated graph takes the form
This graph is not spherical, as is seen by applying Lemma \[4\] successively at the two branch points. On the other hand, this system of curves forms a basis for $H_2(\bar{X})$, and hence by Poincaré duality over $\mathbb{Z}$, the discriminant of this graph is one in absolute value. Denoting this system of curves on $\bar{X}$ by $Y$, with the notations of §2 we see that for small $\delta$, $\bar{X} - V_\delta(Y) = M$ is a contractible compact 4-manifold with boundary $\partial M$ a homology sphere but not a homotopy sphere.

Consider the manifold $M' = M \times [0, 1] \times [0, 1]$ with boundary

$$\partial M' = \partial M \times [0, 1] \times [0, 1] \cup M \times \{0, 1\} \times [0, 1] \cup M \times [0, 1] \times \{0, 1\}.$$ 

Then $M'$ is contractible and $\partial M'$ is a homotopy sphere. By the $h$-cobordism theorem, $\partial M'$ is homeomorphic to a sphere and $M'$ to a disc. It follows from well-known theorems that $X \times \mathbb{R}^2$ is homeomorphic to $\mathbb{R}^6$.

We may thus conclude that either $X$ is an affine rational non-singular surface with $X \times \mathbb{C}$ isomorphic as an algebraic variety to $\mathbb{C}^3$ but $X$ not isomorphic to $\mathbb{C}^2$; or, that there is a non-singular affine rational variety $Y(= X \times \mathbb{C})$ of dimension 3 homeomorphic to $\mathbb{C}^3$ but not isomorphic to $\mathbb{C}^3$. We are unable to decide which of these possibilities holds in fact, or in other words whether $X \times \mathbb{C} \approx \mathbb{C}^3$ or not.

The author wishes to thank M. P. Murthy and C. S. Seshadri for helpful discussions. He is grateful to his sister C. P. Bhamini for her painstaking typing of the manuscript. Finally, he would like to acknowledge several suggestions for improvement of the exposition made by the referee.

Remarks on the Kodaira Vanishing Theorem*

By C.P. Ramanujam

[Received February 22, 1971]

1 Introduction

The object of this note is three-fold. In the first part, we give a de-
duction of the Kodaira-Nakano-Akizuki vanishing theorem [1] from the
Lefschetz hyperplane-section theorem [6], using a lemma of Mumford.
In the second part, we prove a vanishing theorem for the first cohomol-
ogy for varieties in all characteristics. The idea of this section is due to
Franchetta [2], but Franchetta failed to prove the basic Lemma [3]. In the
third part, we return to the case of the complex base-field, and give what
seems to be the most general form known of the Kodaira vanishing the-
orem for the cohomologies of a line bundle in this case. We were told
of the existence of such a generalisation by D. Mumford.

2 The Kodaira-Nakano-Akizuki vanishing theorem

The statement runs as follows:

Theorem 1. Let $X$ be a complex non-singular algebraic variety, and $L$
a line bundle on $X$ such that $L^{-1}$ is ample (in the sense of Grothendieck,
that is, for some $n > 0$, $L^{-n}$ is induced from the hyperplane bundle

---

*This work was done while the author was at the Mathematics Institute, University
of Warwick, with financial assistance from Harvard University.
\( \mathcal{O}_{\mathbb{P}^N}(1) \) by an imbedding \( X \hookrightarrow \mathbb{P}^N \). Then, for \( p + q < \dim X \),

\[
H^q(X, \Omega^p \otimes L) = (0).
\]

For the proof, we need the following simple lemma, whose construction is due to Mumford [7].

**Lemma 1.** Let \( X \) be a variety over the complex field, \( L \) a line bundle on \( X \), \( \sigma \in H^0(X, L^m) - (0) \) where \( m \) is positive integer and \( D \) the divisor of \( \sigma \). Then there is an \( m \)-fold cyclic covering \( f : X' \to X \) ramified precisely over the support of \( D \) such that \( f(L) \) admits a section \( \tau \) satisfying

\[
\tau^m = f^*(\sigma) \quad \text{in} \quad H^0(X', f^*(L^m)).
\]

If further \( X \) and \( D \) are non-singular, so are \( X' \) and \( \text{div.} \tau \), and in the neighbourhood of a point of the support of \( D \), the covering \( f \) is isomorphic to the covering \( \mathbb{C}^n \to \mathbb{C} \) given by

\[
(z_1, z_2, \ldots, z_n) \mapsto (z_1, z_2, \ldots, z_n^m)
\]

restricted to neighbourhoods of the origin.

**Proof.** Define \( X' \) to be the subvariety of the total space of \( L \) given by

\[
X' = \{ x \in L | x^m = \sigma(\pi(x)) \quad \text{in} \quad L^m \}
\]

where \( \pi : L \to X \) is the projection, \( f : X' \to X \) the restriction of \( \pi \), and on \( f^*(L) = L \times X' \), define a section \( \tau : X' \to f^*(L) \) by \( \tau(x) = (x, x) \).

All the conditions are trivially verified. \( \square \)

**Proof of Theorem 1.** We proceed by induction on \( n = \dim X \). The statement being trivial for \( n = 1 \), we assume \( n > 1 \) and that the result holds for varieties of smaller dimension.

By assumption and the theorem of Bertini, there is an integer \( m > 0 \) and \( \sigma \in H^0(X, L^{-m}) \) such that \( D = \text{div.} \sigma \) is a non-singular hyperplane section of \( X \) for some projective embedding. By Lemma 1, \( \exists f : X' \to X \) a cyclic \( m \)-fold covering with \( X' \) non-singular and \( \tau \in H^0(x, f^*(L^{-1})) \) such that \( \tau^m = f^*(\sigma) \) and \( D' = \text{div.} \tau \) is non-singular. Also, \( D' \) is the
support of a hyperplane section of $X'$ for some embedding, since $f^*(L^{-1})$ is ample on $X'$ (E. G. A., Chap. II). By the Lefschetz hyperplane section theorem [6],

$$H^i(X', C) \to H^i(C', C)$$

is an isomorphism for $i < n - 1$ and is injective for $i = n - 1$. By the Hodge decomposition theorem [8], p. 129, it follows that

$$H^p(X', \Omega^q_{X'}) \to H^p(D', \Omega^q_{D'})$$ (1)

is an isomorphism for $p + q < n - 1$ and is injective for $p + q = n - 1$. Let $\mathcal{I}$ be the sheaf of ideals defining $D'$, so that $\mathcal{I}$ is isomorphic to the sheaf of germs of sections of $f^*(L)$. We have the exact sequence (E. G. A., Chap. IV, Pt. 1)

$$0 \to \mathcal{I} \otimes \mathcal{O}_{D'} \to \Omega^1_{X'} \otimes \mathcal{O}_{X'} \to \Omega^1_{D'} \to 0,$$

and hence for any $q > 0$, the exact sequence

$$0 \to \Omega^{q-1}_{D'} \otimes \mathcal{I} \otimes \mathcal{O}_{D'} \to \Omega^q_{X'} \otimes \mathcal{O}_{D'} \to \Omega^q_{D'} \to 0$$

and $\Omega^{q-1}_{D'} \otimes \mathcal{I} \otimes \mathcal{O}_{D'} \approx \Omega^{q-1}_{D'} \otimes f^*(\mathcal{L})$ where as usual we denote by a script letter the sheaf of germs of sections of the line bundle denoted by the same letter in bold type. By induction hypothesis, $H^p(D', \Omega^q_{D'}) = (0)$ for $p + q < n$, so that $H^p(X, \Omega^q_{X} \otimes \mathcal{O}_{D'}) \to H^p(\Omega^q_{D'})$ is an isomorphism for $p + q < n - 1$ and is injective for $p + q = n - 1$. This together with (1) gives us that

$$H^p(X', \mathcal{I} \otimes \Omega^q_{X'}) \to H^p(D', \mathcal{I} \otimes \Omega^q_{D'})$$

is an isomorphism for $p + q < n - 1$ and is injective for $p + q = n - 1$. It follows that

$$H^p(X', f^*(L) \otimes \Omega^q_{X'}) = H^p(X', \mathcal{I} \otimes \Omega^q_{X'}) = (0)$$ (2)

for $p + q < n$. Having proved the theorem for $X'$, it would follow for $X$ and the line bundle $L$ on $X$, provided the inclusion of sheaves $\mathcal{L} \otimes \Omega^q_X \hookrightarrow f_*(f^*(\mathcal{L}) \otimes \Omega^q_X) \approx \mathcal{L} \otimes f_*(\Omega^q_X)$ admits a splitting, or
equivalently, if the natural inclusion \( i : \Omega^q_X \hookrightarrow f_*(\Omega^q_{X'}) \) splits. (This is because the morphism \( f \) is finite, so that for any \( \mathcal{F} \) coherent on \( X' \), \( H^p(X', \mathcal{F}) \approx H^p(X, f_*(\mathcal{F})) \).)

To give a splitting of \( i \), let \( U \) be any open set of \( X \) and \( \omega \) a regular differential form on \( f^{-1}(U) \). Define a form \( \tilde{\omega} \) on \( f^{-1}(U) \) by \( \tilde{\omega} = \sum_{\phi \in G} \phi^*(\omega) \) where \( G \) denotes the Galois groups of \( X' \) over \( X \). Then \( \tilde{\omega} \) is regular and \( G \)-invariant on \( f^{-1}(U) \). We assert that there is a unique form \( Tr \omega \) regular on \( U \) such that \( f^*(Tr \omega) = \tilde{\omega} \). This is in fact clear if \( U \) does not contain any branch points of \( f \). At points of the branch-locus, this follows from a simple calculation using the local description of \( f \) given in Lemma \[\text{[1]}\]. Now, \((1/m) Tr \) gives the required splitting.

3 The method of Franchetta

Let \( X \) be a non-singular variety of dimension \( n \geq 2 \) over an algebraically closed field of any characteristic and \( D \) an effective divisor on \( X \). We define (following Franchetta) \( D \) to be numerically connected if there is an ample \( H \) on \( X \) such that for any decomposition \( D = D_1 + D_2, D_i > 0 \), we have \( (H^{n-2} \cdot D_1, D_2) > 0 \). It is clear that the effective divisor without multiple components is numerically connected if and only if its support is connected, and that for any effective \( D \), if \( nD \) is numerically connected, so is \( D \). Further, if \( H' \) is a generic (hence non-singular) hyperplane section of \( X \) for an embedding given by any multiple of \( H \), \( D \) is numerically connected if and only if \( D, H' \) is numerically connected on \( H' \).

**Lemma 2.** If for some \( N > 0 \), \( ND \) moves in an algebraic system of effective divisors without fixed components, and \( (H^{n-2} \cdot D^2) > 0 \) for some ample \( H \), then \( D \) is numerically connected.

\[\text{[1]}\] In fact, for any separable morphism of non-singular varieties \( f : X' \to X \) one can define a homomorphism

\[ Tr : f_*(\Omega^q_{X'}) \to \Omega^q_i. \]
Proof. By a remark above, we may replace $D$ by $ND$ and assume $N = 1$. By a second remark, we may successively take general hyperplane sections of $X$ for an embedding given by a multiple of $H$, till we arrive at a surface. The other hypotheses are stable for general hyperplane sections.

Thus, assume $X$ a non-singular surface and $D = D_1 + D_2$, $D_i > 0$. Since $D$ moves in an algebraic system without fixed components we have that $(D, D_i) = (D', D_i) \geq 0$ where $D'$ is algebraically equivalent to $D$ and effective, and has no common components with $D$. Since $(D^2) > 0$, at least one of these is a strict inequality. Hence $- (D_1, D_2) \leq (D^2_i)(i = 1, 2)$ with at least one strict inequality. Suppose now that $(D_1, D_2) \leq 0$, so that $0 \leq -(D_1, D_2) \leq (D^2_i)(i = 1, 2)$.

Apply the Hodge index theorem for surfaces (valid in any characteristic, [4]) to the subgroup of the Neron-Severi group generated by $D_1, D_2$. The intersection form must have one positive and one negative eigenvalue on this subspace if the $D_i$ are numerically independent. But if they are numerically dependent, we must have $aD_1 = bD_2$ with $a, b$ positive integers, and since $(D^2) > 0$, $(D_1, D_2) > 0$. Hence they are independent, and we get

$$(D^2_1, D^2_2) - (D_1, D_2)^2 = \det \begin{pmatrix} (D^2_1) & (D_1, D_2) \\ (D_1, D_2) & (D^2_2) \end{pmatrix} < 0,$$

contradicting our earlier inequalities $0 \leq -(D_1, D_2) \leq (D^2_1)$. Hence $(D_1, D_2) > 0$.  

Lemma 3. If $D$ is a numerically connected effective divisor on a non-singular variety $X$, $H^0(D, \mathcal{O}_D)$ consists of constants.

Proof. We proceed by induction on $n = \dim X$. Suppose $n > 2$ and the result holds in smaller dimensions. Choose an embedding of $X$ in $\mathbb{P}^N$ such that $H^0(D, \mathcal{O}_D(-1)) = (0)$. (This is possible since $D$ does not have points as embedded components). Let $H$ be a general hyperplane section. Then we have the exact sequence $0 \to H^0(D, \mathcal{O}_D) \to H^0(D \cap H, \mathcal{O}_{D \cap H})$, and the last group consists of constants, by induction.
hypothesis applied to the pair \((H, D \cap H)\). Hence so does \(H^0(D, \mathcal{O}_D)\), and we are through.

Thus, one has only to prove the lemma when \(\dim X = 2\). Let us suppose there is a section \(\sigma\) of \(H^0(D, \mathcal{O}_D)\) which is not a scalar. Since \(D_{\text{red}}\) is connected, \(H^0(D, \mathcal{O}_{D_{\text{red}}})\) consists of constants, and the image of \(\sigma\) in \(H^0(\mathcal{O}_{D_{\text{red}}})\) is a scalar \(\lambda\). Replacing \(\sigma\) by \(\sigma - \lambda\) we may assume that \(\sigma\) is a section of \(\mathcal{R}\), the root ideal of \(\mathcal{O}_D\). One can evidently find an effective divisor \(D_1\) which is maximum, satisfying the conditions \(0 < D_1 < D\), \(\sigma \in \mathcal{I}_{D_1} \mathcal{O}_D\). Let \(D = D_1 + D_2\). We have two exact sequences of coherent sheaves on \(X\),

\[
0 \to \mathcal{O}_{D_2} \xrightarrow{\sigma} \mathcal{O}_D \to \mathcal{O}_{D}/\sigma \mathcal{O}_D \to 0,
0 \to \mathcal{F} \to \mathcal{O}_{D}/\sigma \mathcal{O}_D \to \mathcal{O}_{D_1} \to 0,
\]

where \(\mathcal{F}\) is a sheaf supported by finitely many points. Calculate Chern classes (in the ring of rational or algebraic equivalence classes of cycles, see [5]). We have

\[
c(\mathcal{O}_D) = c(\mathcal{O}_{D_2}) \cdot c(\mathcal{O}_{D}/\sigma \mathcal{O}_D) = c(\mathcal{O}_{D_2}) \cdot c(\mathcal{O}_{D_1}) \cdot c(\mathcal{F}),
\]

\[
= \frac{1}{1 - D} = \frac{1}{1 - D_1} \cdot \frac{1}{1 - D_2} \cdot c(\mathcal{F}).
\]

If \(\mathcal{F}\) has support at the points \(P_i\) and \(l(\mathcal{F}_{P_i}) = n_i\), we have \(c(\mathcal{F}) = 1 - \sum n_i P_i\). Thus,

\[
(1 - D_1) \cdot (1 - D_2) = (1 - D) \cdot (1 - \sum n_i P_i),
(D_1, D_2) = - \sum n_i \leq 0.
\]

\[\square\]

**Lemma 4.** † Let \(f : X' \to X\) be a proper birational morphism of a non-singular surface \(X'\) onto a normal surface \(X\), and \(L\) a line bundle on \(X'\) such that for any irreducible curve \(C\) on \(X'\) contracted to a point by \(f\), \((C, c_1(L)) \geq 0\). Then, \((R^1 f)(\Omega^2_X, \otimes L) = 0.\)

† Analogous results have been obtained over the complex field by Grauert, also in the case of higher dimensions.
Proof. The sheaf $R^1 f(\Omega^2_X \otimes L)$ is concentrated at the finitely many points $P$ where $\dim f^{-1}(P) = 1$. Let $P$ be one of these points. If we can show that for any effective divisor $D$ with support $f^{-1}(P)$, we have $H^1(D, L \otimes \Omega^2_X, I_D \Omega^2_X) = 0$, it would follow from the ‘Théorème fondamentale des morphismes propres’ (E. G. A., Chap.III) that $R^1 f(\Omega^2_X \otimes L)_P = (0)$ and we would be through. Now, the sheaf $\omega_D = I_D^{-1} \Omega^2_X / \Omega^2_X$ is dualising on $D$, so that we have to show that $H^0(D, L^{-1} \otimes I_D^{-1} \Omega^2_X / \Omega^2_X) = 0$. If not, let $\sigma$ be an non-zero element of $H^0(D, L^{-1} \otimes I_D^{-1} \Omega^2_X / \Omega^2_X)$. We can find a maximum divisor $D_1$ with $0 \leq D_1 \leq D$ such that $\sigma \in H^0(D, L^{-1} \otimes I_D^{-1} \Omega^2_X / \Omega^2_X)$, and since $\sigma \neq 0$, $D_1 \neq D$. It then follows that $\sigma$ generates $L^{-1} \otimes I_D^{-1} \Omega^2_X / \Omega^2_X$ generically on the components of the support of this sheaf. If we set $D_2 = D - D_1$, this sheaf is nothing but $L^{-1} \otimes I_{D_2}^{-1} \Omega^2_X$. Further, the annihilator of $\sigma$ is easily seen to be $I_{D_2}$, so that we get an exact sequence

$$0 \rightarrow \mathcal{O}_{D_2} \xrightarrow{\sigma} L^{-1} \otimes I_{D_2}^{-1} \Omega^2_X / \Omega^2_X \rightarrow \mathcal{F} \rightarrow 0$$

where $\mathcal{F}$ has zero dimensional support. Calculating Chern classes, we get

$$c(L^{-1} \otimes I_{D_2}^{-1} \Omega^2_X / \Omega^2_X) = c(\mathcal{O}_{D_2}). c(\mathcal{F}),$$

i.e.,

$$(1 - D_2). (1 - c_1(L) + D_2) = (1 - c_1(L)). (1 - \sum n_i P_i),$$

where $P_i$ are the points supporting $\mathcal{F}$ and $n_i = I_{P_i}. (\mathcal{F}_{P_i})$. This gives

$$(D_2^2) \geq (D_2^2) - (c_1(L). D_2) = \sum n_i \geq 0,$$

which is impossible, since by a well-known result [9], for any nonzero divisor $E$ with support in $f^{-1}(P)$, $(E^2) < 0$. This is a contradiction. □

Lemma 5. Let $X$ be a non-singular complete surface and $L$ a line bundle on $X$ such that for some $n > 0$, the complete linear system determined by $H^0(X, L^n)$ has no fixed components and is not composite with a pencil. Then $H^1(X, L^{-N}) = 0$ for all large $N$. 

Remarks on the Kodaira Vanishing Theorem
Proof. By ([10], Theorem 6.2), we may assume that the linear system determined by $H^0(X, L^n)$ has no base points at all. Hence, there is a morphism $\phi : X \to \mathbb{P}^m$ for some $m > 0$ such that $Y = \phi(X)$ is a surface and $L^n \simeq \phi^*(O_{\mathbb{P}^m}(1))$. Further, by (E.G.A., Chap. II), we may assume $Y$ normal and $\phi$ birational. Determine $N_0$ so that for $N \geq N_0$ and $0 \leq v < n$, $H^1(R^0(\phi(\Omega^2_X \otimes L^v) \otimes O_Y(N))) \simeq H^1(R^0(\phi(\Omega^2_X \otimes L_{N+v})) = 0).$ For any curve $C$ contracted to a point by $\phi$, the restriction of $L^n$ to $C$ is trivial, hence $(c_1(L), C) = 0$. Thus by Lemma 4, $R^1(\phi(\Omega^2_X \otimes L^v) = 0$ for $v \geq 0$. It follows from the Leray spectral sequence that $H^1(X', \Omega^2_{X'} \otimes L_{N+v}) = 0$ for $0 \leq v < n$, $N \geq N_0$; and the lemma follows by Serre duality.

□

Lemma 6. Let $X$ be a complete normal variety. Assume further in the case of positive characteristic that the Frobenius homomorphism on $H^1(X, \mathcal{O}_X)$ is injective. For any effective divisor $D$ on $X$, define $\alpha(D)$ to be the dimension of the kernel of the homomorphism $H^1(X, \mathcal{O}_X) \to H^1(D, \mathcal{O}_D)$. Then, $\alpha(D) = \alpha(D_{\text{red}})$.

Proof. It is clearly sufficient to show that if $D_1 \leq D_2 \leq 2D_1$, $\alpha(D_1) = \alpha(D_2)$.

First suppose that the characteristic is zero. Since the ideal $\mathcal{I}_{D_1} \mathcal{O}_{D_2}$ is of square zero, we have the exact sequence $0 \to \mathcal{I}_{D_1} \mathcal{O}_{D_2} \to \mathcal{O}^*_{D_2} \to \mathcal{O}^*_{D_1} \to 1$ from which the exact sequence

$$H^0(\mathcal{O}^*_{D_1}) \to H^1(\mathcal{I}_{D_1} \mathcal{O}_{D_2}) \to \text{Pic } D_2 \to \text{Pic } D_1.$$
it is so on any quotient, and the image of $H^1(\mathcal{O}_X) \to H^1(\mathcal{O}_D)$ cannot meet $\text{Ker} \lambda$.

\begin{remark}
An ‘evaluation’ of $\alpha(D)$ has been given by Kodaira when $X$ is a surface in characteristic zero and $D$ is reduced. We give a rapid derivation of this, valid for any non-singular $X$ in characteristic zero and any effective $D$. We have clearly that $\alpha(D) = \alpha(D_{\text{red}})$ is the dimension of the kernel of $\text{Pic}^0 X \to \text{Pic} D_{\text{red}}$. But if $\eta : X \to A$ is the Albanese map, and $B$ the abelian subvariety of $A$ generated by the differences $\eta(x) - \eta(y)$ where $x$ and $y$ belong to the same connected component of $D_{\text{red}}$, since $\text{Pic}^0 X = \text{Pic}^0 A$, one sees easily (using the Jacobians of normalisations of generic curves on the various components of $D_{\text{red}}$) that the dimensions of the kernels of $\text{Pic}^0 X \to \text{Pic} D_{\text{red}}$ and $\text{Pic}^0 A \to \text{Pic}^0 B$ are the same. But the dimension of this last group equals the dimension of the space of 1-forms on $A$ which induce the 1-form 0 on $B$; and since $D_{\text{red}}$ generates $B$ (in the above sense), it also equals the dimension of the space of 1-forms on $X$ which induce the 1-form 0 on $D_{\text{red}}$. Thus we have
\[
\alpha(D) = \dim \ker (H^0(X, \Omega^1_X) \to H^0(D_{\text{red}}, \Omega^1 D_{\text{red}})).
\]

\textbf{Theorem 2.}
Let $X$ be a non-singular projective variety of dimension $\geq 2$ and $D$ an effective divisor on $X$ such that for some $n > 0$, $|nD|$ has no fixed components and is not composite with a pencil. Assume further that either the characteristic is zero or that it is positive and that the Frobenius is injective on $H^1(\mathcal{O}_X)$. Then $H^1(\mathcal{O}_X(-D)) = (0)$.

\textit{Proof.}
First suppose $\dim X = 2$. The exact sequence
\[
0 \to \mathcal{O}_X(-D) \to \mathcal{O}_X \to \mathcal{O}_D \to 0
\]
leads to the cohomology sequence
\[
H^0(X, \mathcal{O}_X) \to H^0(D, \mathcal{O}_D) \to H^1(X, \mathcal{O}_X(-D)) \to H^1(X, \mathcal{O}_X) \to H^1(D, \mathcal{O}_D)
\]
and the result follows from Lemmas 2, 3, 5 and 6.

Next suppose $n = \dim X > 2$ and that the result holds in smaller dimensions. Replacing the given projective embedding by the one given
by hypersurfaces of sufficiently large degree, we may assume that $H^1(X, \mathcal{O}_X(-D)(-1)) = (0)$. Hence if $H$ is a general hyperplane section for this embedding, the homomorphism $H^1(X, \mathcal{O}_X(-D)) \to H^1(H, \mathcal{O}_H(-D_H))$ is injective. On the other hand, the assumptions fulfilled by $D$ on $X$ are also fulfilled by $D_H$ on $H$. This completes the induction. □

4 A generalisation of the Kodaira vanishing theorem for algebraic varieties

We assume the following theorem:

**Theorem [11]**. Let $X$ be a projective variety over the complex field, $L$ a line bundle on $X$ such that there is an integer $n > 0$ and a birational morphism $\phi : X \to Y \subset \mathbb{P}^N$ such that $\phi^*(\mathcal{O}_Y(1)) \approx L$. Then $H^i(X, L^{-1}) = 0$ for $0 \leq i < \dim X$.

We deduce from this the following

**Theorem 3**. Let $X$ be a projective non-singular variety of dimension $n$ over the complex field, $L$ a line bundle on $X$, $m$ an integer with $1 \leq m \leq n$ such that for some $N > 0$, the complete linear system determined by $H^0(X, L^N)$ has the dimension of its base point set $\leq n - m$ and has a projective image of dimension $\geq m$. Then $H^i(X, L^{-1}) = (0)$ for $0 \leq i < m$.

*Proof.* We fix $m$, and use induction on $n$ starting from $n = m$. Assume first that $n > m$ and that the theorem is true for varieties of dimension $n - 1$. Using a suitable projective embedding, we may assume that $H^i(X, L^{-1}(-1)) = (0)$ for $0 \leq i < n$. If $H$ is a general hyperplane section for this embedding, it follows that $H^i(X, L^{-1}) \to H^2(H, (L_H)^{-1})$ is injective for $0 \leq i < n$, where $L_H$ denotes the restriction of $L$ to $H$. Further, the hypotheses made on the pair $(X, L)$ are evidently also satisfied by the pair $(H, L_H)$ for $H$ general. We are thus reduced to proving the theorem when $n = m$.

Thus, assume $n = m$. Since the base points of the complete linear system determined by $H^0(X, L^N)$ are isolated, by ([10], Theorem...
6.2), replacing $N$ by a larger multiple, we may assume there are no base points. Thus there is a morphism $\phi : X \to Y \subset P^k$ with $\dim X = \dim Y = n$ such that $\phi^*(\mathcal{O}_Y(1)) \approx L^N$. By (E.G.A. Chap II), we may even assume $\phi$ birational. But now, the result follows from the theorem quoted above. □

**Remarks.** (1) It is not clear if in Theorem 3, the hypothesis on the set of base points of the complete linear system determined by $H^0(X, L^N)$ can be weakened to the assumption that the base point set be of dimension $\leq n - 2$.

For $m = 2$, Theorem 3 specialises to Theorem 2 over $\mathbb{C}$, which however is proved under the further assumption that $H^0(X, L) \neq (0)$.

(2) A generalisation of the theorem of Nakano on the vanishing of $H^p(X, \Omega^q \otimes L^{-1})$ along the lines of the theorem quoted at the beginning of this section does not exist. In fact, let $\sigma : X \to P^3$ be the morphism obtained by blowing up $P^3$ at $(1, 0, 0, 0)$, and $L = \sigma^*(\mathcal{O}_{P^3}(1))$. Then one shows easily that $H^1(X, \Omega^1_X \otimes L^{-1}) \neq (0)$.

The Invariance of Milnor’s Number Implies The Invariance of the Topological Type

By Lê Dũng Tráng and C. P. Ramanujam.

Introduction. We are interested in analytic families of $n$-dimensional hypersurfaces having an isolated singularity at the origin. In this paper we only consider the case when the Milnor’s number of the singularity at the origin does not change in this family. Under this hypothesis with $n = 1$, H. Hironaka conjectured that the topological type of the singularity does not change. We give a proof of this conjecture in the more general case of $C^\infty$ family of $n$-dimensional hypersurfaces of dimension $n \neq 2$. The hypothesis $n \neq 2$ comes from the fact we are using $h$-cobordism theorem. Actually a more general conjecture should be the following:

0.1 let $F(z_0, \ldots, z_n, t)$ be analytic in the $z_i$ and smooth (i.e. $C^\infty$) in $t$. Suppose that for any $t_0 \in \mathbb{R}$ the complex hypersurface $F(z_0, \ldots, z_n, t_0) = 0$ of $\mathbb{C}^{n+1}$ has an isolated singularity at the origin. Suppose that the Milnor’s number $\mu_{t_0}$ of this singularity, say the complex dimension of $\mathbb{C}\{z_0, \ldots, z_n\}/(\partial F_{t_0})$ is the ideal generated by the partial derivatives $(\partial F/\partial z_i)(z_0, \ldots, z_n, t_0)$ ($i = 0, \ldots, n$) in this algebra, does not depend on $t_0$. Then the pair composed of the smooth part of the hypersurface $F = 0$ in a neighborhood $U$ of 0 in $\mathbb{C}^{n+1} \times \mathbb{R}$ and $(\{0\} \times \mathbb{R}) \cap U$ satisfies Whitney conditions at each point of $(\{0\} \times \mathbb{R}) \cap U$, (cf. [17] p. 540).

If such a conjecture is true we obtain easily our result by using Thom-Mather isotopy theorem (cf. [16] and [7]).
Actually recent results of B. Teissier [14] give a numerical condition to get Whitney conditions. Precisely let \((X, x)\) be a germ of hypersurface in \(\mathbb{C}^{n+1}\) with an isolated singularity, let \(E\) be a \(k\)-dimensional affine subspace of \(\mathbb{C}^{n+1}\) passing through \(x\). If \(E\) is chosen sufficiently general the Milnor’s number of \(X \cap E\) at \(x\) does not depend on \(E\), we denote this number by \(\mu^{(k)}(X, x)\). Then B. Teissier proved that if in an analytic family of germs of hypersurfaces \((X_t, 0)\) in \(\mathbb{C}^{n+1}\) defined by \(F(z_0, \ldots, z_n, t) = 0\) and having an isolated singularity at the origin \(0\) the numbers \(\mu^{(k)}(X_t, 0)\) for \(1 \leq k \leq n + 1\) do not depend on \(t\), the smooth part of the hypersurface \(F(z_0, \ldots, z_n, t) = 0\) in a neighborhood \(U\) of \(0\) in \(\mathbb{C}^3\) satisfies Whitney conditions along \((\{0\} \times \mathbb{C}) \cap U\).

When \(n = 1\) our result shows that the multiplicity of the curves of our analytic family is constant, because in this case we know that the multiplicity of a plane curve singularity is a topological invariant.

Actually when \(n = 1\), O. Zariski in [19] and [20] proved that if the sum of \(\mu_t + m_t - 1\), where \(\mu_t\) is the Milnor’s number of the singularity and \(m_t\) its multiplicity, is independent of \(t\) then the smooth part of the surface \(F(x, y, t) = 0\) in a neighborhood \(U\) of \(0\) in \(\mathbb{C}^3\) satisfies Whitney conditions along \((\{0\} \times \mathbb{C}) \cap U\). In his terminology the preceding surface is equisingular along its singular locus at \(0\). Then the constancy of \(\mu_t\) implying the one of \(m_t\), Teissier’s result is analogous to Zariski’s result.

0.2 It is then natural to conjecture, following B. Teissier (cf. [14]) that the constancy of the \(\mu^{(n+1)}_t\) implies the constancy of the \(\mu^{(k)}_t(1 \leq k \leq n)\), which would imply (0.1). Recently J. Brianson and J. P. Speder disproved this conjecture.

1 Milnor’s Results on the Topology of Hypersurfaces

In this paragraph we first recall Milnor’s results on the topology of hypersurfaces (cf. [9]).

Let \(f : U \subset \mathbb{C}^{n+1} \to \mathbb{C}\) be an analytic function on an open neigh-
borhood $U$ of 0 in $\mathbb{C}^{n+1}$. We denote

$$B_\epsilon = \{z|z \in \mathbb{C}^{n+1} : ||z|| \leq \epsilon\}$$

$$S_\epsilon = \partial B_\epsilon = \{z|z \in \mathbb{C}^{n+1} : ||z|| = \epsilon\}.$$

Then:

**Theorem 1.1.** For $\epsilon > 0$ small enough the mapping $\varphi_\epsilon : S_\epsilon \rightarrow S^1$ defined by $\varphi_\epsilon(z) = f(z)/|f(z)|$ is a smooth fibration.

**Theorem 1.2.** For $\epsilon > 0$ small enough and $\epsilon \gg \eta > 0$ the mapping $\psi_{\epsilon,\eta} : \hat{B} \cap f^{-1}(\partial D_\eta) \rightarrow S^1$ defined by $\psi_{\epsilon,\eta}(z) = f(z)/|f(z)|$, where $\partial D_\eta = \{z|z \in \mathbb{C} : |z| = \eta\}$, is a smooth fibration isomorphic to $\varphi_\epsilon$ by an isomorphism which preserves the arguments. We call the fibrations of Theorems 1.1 and 1.2 the Milnor’s fibrations of $F$ at 0.

**Corollary 1.3.** The fibers of $\varphi_\epsilon$ have the homotopy type of a $n$-dimensional finite CW-complex.

**Theorem 1.4.** For $\epsilon > 0$ small enough, $S_\epsilon$ transversally cuts the smooth part of the algebraic set $H_0$ defined by $f = 0$. If 0 is an isolated critical point of $f$, then the pairs $(S_\epsilon, S_\epsilon \cap H_0)$ for any $\epsilon$ small enough are diffeomorphic and $(B_\epsilon, B_\epsilon \cap H_0)$ is homeomorphic to $(B_\epsilon, C(S_\epsilon \cap H_0))$, where $C(S_\epsilon \cap H_0)$ is the real cone, union of segments with vertices at 0 and at a point of $S_\epsilon \cap H_0$.

Theorem 1.4 says that, when 0 is an isolated critical point of $f$, for $\epsilon > 0$ small enough, the topology of the pair $(B_\epsilon, B_\epsilon \cap H_0)$ does not depend on $\epsilon$. Then if $g$ is another analytic function defined in a neighborhood of 0, having an isolated critical point at 0, we say that the hypersurfaces $H_0$ and $H'_0$ defined by $f = 0$ and $g = 0$ have the same topological type at 0 if for $\epsilon > 0$ small enough there is a homeomorphism $(B_\epsilon, B_\epsilon \cap H_0) \sim (B_\epsilon, B_\epsilon \cap H'_0)$.

From [9] and [11] we have:

**Theorem 1.5.** If 0 is an isolated critical point of $f$, for $\epsilon > 0$ small enough, the fibers of $\varphi_\epsilon$ have the homotopy type of a bouquet of $\mu$ spheres of dimension $n$ with

$$\mu = \dim_{\mathbb{C}}(\mathbb{C}\{z_0, \ldots, z_n\}/(\partial f/\partial z_0, \ldots, \partial f/\partial z_n)).$$
(A bouquet of spheres is the topological space union of spheres having a single point in common).

We call the number of spheres the Milnor’s number of the critical point 0 of \( F \) or the number of vanishing cycles of \( F \) at 0.

Actually we have:

**Proposition 1.6.** The germ of morphism \( \psi : (\mathbb{C}^{n+1}, 0) \to (\mathbb{C}^{n+1}, 0) \) whose components are the partial derivatives of \( f \) is an analytic covering of degree \( \mu \). On another hand, for \( \epsilon > 0 \) small enough, the mapping \( \psi_\epsilon : S_\epsilon \to S^{2n+1} \) defined by

\[
\psi_\epsilon(z) = \left( \frac{\partial f}{\partial z_0}(z), \ldots, \frac{\partial f}{\partial z_n}(z) \right) / \sqrt{\sum_{i=0}^{n} |\frac{\partial f}{\partial z_i}(z)|^2}
\]

has the degree \( \mu \).

Finally recall a well-known result of P. Samuel (cf. [12]):

**Theorem 1.7.** Let \( f : U \subset \mathbb{C}^{n+1} \to \mathbb{C} \) be an analytic function on a neighborhood \( U \) of 0 in \( \mathbb{C}^{n+1} \). Suppose \( f(0) = 0 \) and 0 is an isolated critical point. Then there exists a polynomial \( f_0 : \mathbb{C}^{n+1} \to \mathbb{C} \) with an isolated critical point at 0 and an analytic isomorphism of a neighborhood \( U_1 \) of 0 onto a neighborhood \( U_2 \) of 0 which sends the points of \( f = 0 \) on points of \( f_0 = 0 \).

# 2 The Main Theorem

We prove the following theorem:

**Theorem 2.1.** Let \( F(t, z) \) be a polynomial in \( z = (z_0, \ldots, z_n) \) with coefficients which are smooth complex valued functions of \( t \in I = [0, 1] \) such that \( F(t, 0) = 0 \) and such that for each \( t \in I \), the polynomials \( \frac{\partial F}{\partial z_i}(t, z) \) in \( z \) have an isolated zero at 0. Assume moreover that the integer

\[
\mu_t = \dim_{\mathbb{C}} \mathbb{C}\{z\}/\left( \frac{\partial f}{\partial z_0}(t, z), \ldots, \frac{\partial f}{\partial z_n}(t, z) \right)
\]
is independent of $t$. Then the monodromy fibrations of the singularities of $F(0, z) = 0$ and $F(1, z) = 0$ at 0 are for the same fiber homotopy. If further $n \neq 2$, these fibrations are even differentiably isomorphic and the topological types of the singularities are the same.

A crucial step in the proof of the theorem is the following lemma:

Lemma 2.2. Let $f \in \mathbb{C}[z_0, \ldots, z_n]$, $f(0) = 0$, and $R > 0$, $\varepsilon > 0$ such that

(i) $\dim_{\mathbb{C}} \mathbb{C}\{z_0, \ldots, z_n\}/(\partial f/\partial z_0, \ldots, \partial f/\partial z_n) = \mu < \infty$;

(ii) for any $z$ with $0 < ||z|| < R$ and $|f(z)| \leq \varepsilon$, we have $d f \neq 0$;

(iii) for any $z \in S_R = \{z \mid ||z|| = R\} \text{ with } |f(z)| \leq \varepsilon$, $d(f|_{S_R})$ is of rank 2;

(iv) for some $w_0$ with $0 < |w_0| \leq \varepsilon$, $F_{w_0} = \{z \mid ||z|| \leq R, f(z) = w_0\}$ is of the homotopy type of a bouquet of $\mu$ n-spheres.

Then the map

$$\{z \mid ||z|| \leq R, |f(z)| = \varepsilon\} \xrightarrow{f/|f|} S^1$$

(A)

is a fibration fiber homotopy equivalent to the monodromy fibration of the singularity of $f = 0$ at 0. If further $n \neq 2$, it is even diffeomorphic to the monodromy fibration, and there is a homeomorphism of the set

$$\{z \mid ||z|| \leq R, |f(z)| = \varepsilon\} \cup \{z \mid ||z|| = R, |f(z)| \leq \varepsilon\}$$

with the sphere $\{z \mid ||z|| = \delta\}$ ($\delta$ small) which maps the set $\{z \mid ||z|| = R, f(z) = 0\}$ onto the set $\{z \mid ||z|| = \delta, f(z) = 0\}$.

Proof. It is clear from (ii) and (iii) that the map

$$f : \{z \mid ||z|| \leq R, 0 < |f(z)| \leq \varepsilon\} \to \{w \mid 0 < |w| \leq \varepsilon\}$$

(B)

is a locally trivial differentiable fibration, hence so is (A). Choose $\delta, \eta$ with $0 < \delta < R$, $0 < \eta < \varepsilon$ such that

$$f/|f| : \{z \mid ||z|| \leq \delta, |f(z)| = \eta\} \to S^1$$

(C)
is the monodromy fibration of the singularity. This fibration is contained in the fibration

\[ f/|f| : \{ z \mid \| z \| \leq R, |f(z)| = \eta \} \rightarrow S^1, \tag{D} \]

and (A) and (D) are diffeomorphic fibrations since (B) has been shown to be a fibration. Thus it suffices to show that the inclusion of (C) in (D) is a fiber homotopy equivalence. By the theorem of Dold ([4] Theorem 6.3) and the homotopy sequence of a fibration, it suffices to show that the inclusion of the fiber \( G_1 \) over 1 of (C) in the fiber \( F_1 \) over 1 of (D) is a homotopy equivalence. Now, since the spheres \( S_R \) and \( S_\delta \) of radii \( R \) and \( \delta \) respectively are transversal to the manifold \( f(z) = \eta \), for all \( z_0 \) close enough to the origin, the pair of manifolds with boundaries \( (F_1, G_1) \) is diffeomorphic to the pair

\[ (\{ z | f(z) = \eta, \| z - z_0 \| \leq R \}, \{ z/|f(z) = \eta, \| z - z_0 \| \leq \delta \}). \]

Choose such \( z_0 \) such that the distance function \( \| z - z_0 \| \) has only nondegenerate critical points on \( f(z) = \eta \). Since the indices of this function at these critical points are \( \leq n \), it follows that \( F_1 \) is obtained from \( G_1 \), up to homotopy type, by attaching cells of dimension \( \leq n \). Now, it follows from (iv) that \( F_1 \) is of the homotopy type of the wedge \( \mu \) \( n \)-spheres, and the same holds of \( G_1 \), by [9]. It clearly follows that for \( n = 1 \), the inclusion \( G_1 \hookrightarrow F_1 \) is a homotopy equivalence. For \( n > 1 \), both spaces are simply connected, and it suffices to show that \( H_i(G_1, \mathbb{Z}) \rightarrow H_i(F_1, \mathbb{Z}) \) is an isomorphism for all \( i \). This is clearly so for \( i \neq n \) and it also holds for \( i = n \) since \( H_{n+1}(F_1, G_1; \mathbb{Z}) = 0 \), \( H_n(G_1, \mathbb{Z}) \) and \( H_n(F_1, \mathbb{Z}) \) are both free of rank \( \mu \) and \( H_n(F_1, G_1; \mathbb{Z}) \) is torsion-free.

We have thus shown that the inclusion of (C) in (D) is a homotopy equivalence. We have yet to establish the stronger assertions of the lemma for \( n \neq 2 \). First notice that if \( X = \{ z | \delta \leq \| z \| \leq R, |f(z)| \leq \eta \} \), then \( f : X \rightarrow \{ w | |w| \leq \eta \} \) is a differentiable fibration. This follows from (ii), (iii) and the fact that \( d(f|S_\delta) \) is of rank 2 on \( X \cap S_\delta \). It follows that \( X \) is diffeomorphic to a product of the disc \( \{ w | |w| \leq \eta \} \) and the fiber \( X_w \) of \( X \) over any point \( w \) of this disc, in particular \( X_\eta = F_1 - \text{Int} G_1 \). Now, \( H_\ast(F_1, G_1; \mathbb{Z}) = H_\ast(X_\eta, \partial G_1; \mathbb{Z}) = (0) \). So that
\(H_\ast(\partial G_1, \mathbb{Z}) \rightarrow H_\ast(X_\eta; \mathbb{Z})\) is an isomorphism. For \(n = 1\), it follows from this and the classification of surfaces with boundary that \(X_\eta\) is diffeomorphic to \(I \times \partial G_1\). For \(n > 2\), \(\partial G_1\) is simply connected (\([9]\)) and the inclusion \(\partial G_1 \subset X_\eta\) is a homotopy equivalence. Further, by considering the Morse function \(-||z - z_0||\) with \(z_0\) close to the origin, and noticing that its indices at critical points on \(F_1\) are \(\geq n\), (\([11]\)) we see that \(\pi_1(\partial F_1) \rightarrow \pi_1(F_1)\) is injective, so that \(\partial F_1\) is also simply connected. If we can show that \(H_\ast(X_\eta, \partial F_1; \mathbb{Z}) = 0\), it would follow that the inclusion \(\partial F_1 \hookrightarrow X_\eta\) is a homotopy equivalence. From the homology exact sequence of the triple \((F_1, X_\eta, \partial F_1)\), it suffices to show that \(H_\ast(F_1, \partial F_1) \rightarrow H_\ast(F_1, X_\eta)\) is an isomorphism, or passing to cohomology, that \(H_c^\ast(\text{Int } G_1) \rightarrow H_c^\ast(\text{Int } F_1)\) is an isomorphism, where \(H_c^\ast\) denotes cohomology with compact support. By Poincare duality, this is the same as saying that \(H_\ast(G_1, \mathbb{Z}) \rightarrow H_\ast(F_1, \mathbb{Z})\) is an isomorphism, which is certainly true.

Thus, the inclusions \(\partial G_1 \subset X_\eta\) and \(\partial F_1 \subset X_\eta\) are homotopy equivalences, the spaces are simply connected and we are in real dimensions \(\geq 6\). It follows from the \(h\)-cobordism theorem (\([8]\)) that \(X_\eta\) is diffeomorphic to \(I \times \partial G_1\). Thus, the fibration (D) is obtained from the fibration (C) (which restricted to the boundary of the total space of (C) is trivial) by attaching \(S^1 \times \text{collar}\). Hence the two fibrations are diffeomorphic by a diffeomorphism \(\varphi\). Further, if we fix a diffeomorphism \(X \xleftarrow{\lambda} D \times I \times \partial G_1\) over \(D\), where \(D\) denotes the disc \(\{w| |w| \leq \eta\}\), we may assume that the points \(\lambda(w, 0, x)\) and \(\lambda(w, 1, x)\) correspond to each other under \(\varphi\). But now, the canonical diffeomorphism of \(D \times 0 \times \partial G_1\) and \(D \times 1 \times \partial G_1\) goes over by \(\lambda\) into a diffeomorphism of \(\{z| |z| = \delta, |f(z)| \leq \eta\}\) onto \(\{z| |z| = R, |f(z)| \leq \eta\}\) such that \(\varphi\) and \(\psi\) are equal at points where both are defined and \(\psi\) carries the zero set of \(f\) (i.e., \(\lambda(0 \times 0 \times \partial G_1)\)) in its domain onto the zero set of \(f\) (i.e., \(\lambda(0 \times 1 \times \partial G_1)\)) in its range. Now, by (\([9]\)) there is a homeomorphism of \(\{z| |z| \leq \delta, |f(z)| = \eta\} \cup \{z| |z| = \delta, |f(z)| \leq \eta\}\) onto \(S_\delta\) which is the identity on the second of these sets. This establishes the last assertion of the lemma, except for the fact that \(\epsilon\) is replaced by \(\eta\). But this clearly does not matter, in view of assumptions (ii) and (iii).
Q.E.D.

We need another simple lemma:

**Lemma 2.3.** Let $K$ be a compact convex set in $\mathbb{C}^{n+1}$ and $g_1, \ldots, g_{n+1}$ holomorphic functions in a neighborhood of $K$ such that on $\text{Bd} K$, $\sum |g_i|^2 > 0$. Orient $\text{Bd} K$ (which is homeomorphic to $S^{2n+1}$) such that a radial projection onto an interior sphere has degree $+1$. Then the $g_i$ have only finitely many common zeros in $K$, and the degree $\mu$ of the map $\partial K \to S^{2n+1}$ given by $z \mapsto (\sum |g_i(z)|^2)^{-1/2} (g_1(z), \ldots, g_{n+1}(z))$ equals $\sum_{p \in K} \mu_p$, where

$$\mu_p = \dim \mathcal{O}_{\mathbb{C}^{n+1}}/(g_1, \ldots, g_{n+1}).$$

**Proof.** Since the $g_i$ have no common zeros on $\text{Bd} K$, their common zeros in $K$ form an analytic set in $\mathbb{C}^{n+1}$, and $K$ being compact, they must be a finite set. We proceed by induction on the number $N$ of these common zeros. If $N = 1$, let $P \in \text{Int} K$ be the unique common zero, $B$ a small around $P$ contained in $\text{Int} K$ and $S$ the boundary of $B$. The map $\text{Bd} K \to S^{2n+1}$ is then homotopic to the composite $\text{Bd} K \xrightarrow{\alpha} S = \text{Bd} B \to S^{2n+1}$ where $\alpha$ is radial projection and the map $\text{Bd} B \to S^{2n+1}$ is the map defined above with $K$ replaced by $S$. The result then follows from [9].

If $N > 1$, choose a hyperplane $H$ such that there are no common zeros of the $g_i$ on $H$ and such that if $H^+$ and $H^-$ are the closed half-spaces defined on $H$, $H^+ \cap K$ and $H^- \cap K$ each contain at least one common zero of the $g_i$. Since we may assume by induction that the result holds for each of the compact convex sets $H^+ \cap K$ and $H^- \cap K$, we have only to show that the degree of $\text{Bd} K \to S^{2n+1}$ equals the sum of the degrees of $\text{Bd}(K \cap H^+) \to S^{2n+1}$ and $\text{Bd}(K \cap H^-) \to S^{2n+1}$. Since the intersection $\text{Bd}(K \cap H^+) \cap \text{Bd}(K \cap H^-)$ is contractible on each of these boundaries, the assertion reduces to the standard and easy fact that if $f, g : S^{2n+1} \to S^{2n+1}$ are maps preserving some base point, $h : S^{2n+1} \to S^{2n+1} \vee S^{2n+1}$ the pinching map, the composite $S^{2n+1} \xrightarrow{h} S^{2n+1} \vee S^{2n+1} \xrightarrow{(f,g)} S^{2n+1}$ has degree equal to the sum of the degrees of $f$ and $g$. Q.E.D.
Proof of Theorem 2.1. We set \( f_t(z) = F(t, z) \). It is clearly enough to prove the theorem with \( I \) replaced by some smaller interval \([0, \delta]\) with \( \delta > 0 \). Denote by \( \mu \) the constant value of \( \mu_t, t \in I \). Choose \( R \) and \( \epsilon \) such that the conditions (ii), (iii) and (iv) hold with \( f \) replaced by \( f_0 \), and also such that \( \sum_{i=1}^{n+1} |\partial f_0/\partial z_i|^2 > 0 \) on \( ||z|| = R \). By continuity, one sees that there is a \( \delta > 0 \) such that for any \( t \in [0, \delta] \), (iii) holds and also \( \sum_{i=1}^{n+1} |\partial f_t/\partial z_i|^2 > 0 \) on \( ||z|| = R \). The maps \( S_R \to S^{2n+1} \) are defined by \( ||\text{grad } f_t||^{-1} \). \((\partial f_t/\partial z_i, \ldots, \partial f_t/\partial z_{n+1})\) for various \( t \) are all homotopic, hence all of the degree \( \mu \). On the other hand, we know that at the origin, \( \dim_{\mathbb{C}} C\{z\}/(\partial f_t/\partial z_1, \ldots, \partial f_t/\partial z_{n+1}) = \mu \). It follows from Lemma 2.3 that (ii) is also fulfilled by \( f_t, R \) and \( \epsilon \) if \( t \in [0, \delta] = I_1 \).

Let \( X = \{(t, z) \in I_1 \times \mathbb{C}^{n+1} | ||z|| \leq R, 0 < |F(t, z)| \leq \epsilon\} \), and define \( \Phi : X \to I_1 \times \{w | 0 < |w| \leq \epsilon\}, \Phi(t, z) = (t, F(t, z)) \). Then \( \Phi \) has compact fibers, and is of maximal rank on the sets \( \{(t, z \in X | ||z|| \leq R)\} \) as well as when restricted \( X \cap I_1 \times S_R^{2n+1} \). Thus, \( \Phi \) is a differentiable fibration. Similarly, if \( Y : \{(t, z) \in I_1 \times S_R | |F(t, z)| \leq \epsilon\} \), the map \( \psi : Y \to I_1 \times \{w | |w| \leq \epsilon\}, \psi(t, z) = (t, F(t, z)) \) is a smooth fibration. It follows that \( \psi \) is differentiably a trivial fibration, and that \( \Phi|X \cap (0 \times \mathbb{C}^{n+1}) : X \cap (0 \times \mathbb{C}^{n+1}) \to \{w | 0 < |w| \leq \epsilon\} \) and \( \Phi|X \cap (\delta \times \mathbb{C}^{n+1}) : X \cap (\delta \times \mathbb{C}^{n+1}) \to \{w | 0 < |w| \leq \epsilon\} \) are smoothly isomorphic fibrations such that this isomorphism is compatible with the chosen trivialisation of \( \psi \).

The theorem now follows from Lemma 1. Q.E.D.

We now deduce some corollaries. In order to shorten statements we introduce the following definition. We say that the isolated hypersurface singularities at \( 0 \) in \( \mathbb{C}^{n+1} \) defined by the equations \( f = 0 \) and \( g = 0 \) are of the same type if (i) their monodromy fibrations are fiber homotopic, and (ii), for \( n \neq 2 \), these fibrations are differentiably isomorphic, and there is a homeomorphism of \( S^{2n+1} \) onto itself carrying the zero set of \( f \) on \( S^{2n+1} \) onto that of \( g \), this implies in particular that the matrices of the monodromy transformations on the \( n \)-th homology of the fiber of the Milnor’s fibrations of \( f \) and \( g \) are inner conjugate in \( \text{SL}(\mu, \mathbb{Z}) \), \( \mu \) being the number of vanishing cycles.

Corollary 2.4. Let \( f \in \mathbb{C}[z_1, \ldots, z_{n+1}] \), and \( p_i \in \mathbb{Z}, p_i > 0 (1 \leq i \leq n+1) \).
1) be weights for the variables $z_i$, $f = f_N + f_{N+1} + \ldots$ the decomposition of $f$ into quasi-homogeneous polynomials $f_p$ of weight $p$ with $f_N \neq 0$, suppose $0$ is an isolated critical point of $f_N = 0$. Then the same holds for $f = 0$, and the singularities $f = 0$ and $f_N = 0$ at $0$ are of the same type.

**Proof.** Put $F(t, z) = f_N + tf_{N+1} + t^2f_{N+2} + \cdots$, so that for $t \neq 0$, $F(t, z) = t^{-N}f(t^{p_1}z_1, \ldots, t^{p_{n+1}}z_{n+1})$. Choose $R$ so that $(df_N)_{z} \neq 0$ for $0 < \|z\| \leq R$, and let $\mu = \dim \mathbb{C}\{z\}/(\partial f_N/\partial z_1, \ldots, \partial f_N/\partial z_{n+1})$. Then for $t$ close enough to $0$, $d_zF(t, z) \neq 0$ on $\|z\| = R$, so that $F(t, z)$ has only isolated critical points in $\|z\| \leq R$. Since $F(t, z)$ derives from $f(z)$ by a trivial coordinate transformation, $f(z)$ has $0$ for an isolated critical point. Now choose $R_1 > 0$ such that both $f$ and $f_N$ have $0$ as their only critical point in $\|z\| \leq R_1$. Then the same is true of $F(t, z)$ for $0 \leq t \leq 1$. Further for all $t \in [0, 1]$, the maps $S_R \to S_{2n+1}$ given by

$$z \mapsto \|\text{grad}_z F(t, z)\|^{-1} \left( \frac{\partial f_t}{\partial z_1}, \ldots, \frac{\partial f_t}{\partial z_{n+1}} \right)$$

are homotopic, hence have the same degree. It follows from Lemma 2.3 that $\mu = \dim \mathbb{C}\{z\}/(\partial f_t/\partial z_1, \ldots, \partial f_t/\partial z_{n+1})$ is independent of $t$. Now appeal to the theorem. Q.E.D.

**Remark 2.5.** It is in fact possible to make a stronger statement. There is a diffeomorphism $\varphi : S_{\delta} \to S_{\delta}$ ($\delta$ small) isotopic to the identity which maps $K = \{z \in S_{\delta}|f(z) = 0\}$ onto $K_0 = \{z \in S_{\delta}|f_N(z) = 0\}$ and such that for $z \in S_{\delta} - K$, $f(z)/|f(z)| = f_N(\varphi(z))/|f_N(\varphi(z))|$, i.e., $\varphi|S_{\delta} - K$ is a fiber preserving diffeomorphism of the monodromy fibration of $f$ onto that of $f_N$. This holds for all $n \geq 1$ without exception. This is a consequence of the fact that if we define $f_t(z) = F(t, z)$ as above, there is a $\delta > 0$ such that, for any with $0 < \|z\| = \delta$, and any $t \in [0, 1]\text{grad} \log f_t = \lambda$. $z$ with $\lambda$ complex implies that $|arg \lambda| < \pi/4$ and $\|z\| = \delta$, $f_t = 0$ imply that $d(f_t|S_{\delta})z$ is of rank 2.

To state the next corollary, we need a few definitions and facts from commutative algebra. Let $A$ be a noetherian normal local domain of
dimension \( n + 1 \) with maximal ideal \( \mathfrak{M} \), and \( a \) an \( \mathfrak{M} \)-primary ideal. An element \( f \in A \) is said to be integral over \( a \) if it satisfies an equation

\[
f^m + a_1f^{m-1} + \ldots + a_m = 0, \quad a_i \in a^i.
\]

The set \( \bar{a} \) of elements of \( A \) integral over \( a \) form an ideal containing \( a \), called the integral closure of \( a \). (See [13], Appendix 4 and [10] for all properties made use of.) If \( e(a) \) is the multiplicity of \( a \), we have \( e(a) = e(\bar{a}) \) ([10], Theorem 1). Further, if \( R \) runs through all the discrete valuation rings containing \( A \) and having the same quotient field as \( A \), we have \( \bar{a} = \cap R \cdot a \) ([13], Appendix 4, Theorem 3). Finally, let \( \alpha_i(1 \leq i \leq k) \) be elements of \( A \) generating an \( \mathfrak{M} \)-primary ideal \( a \). Then there exists a finite set of polynomials \( P_\alpha(x_{ij}) \) over the residue field in the variables \( x_{ij}(1 \leq i \leq k, 1 \leq j \leq n + 1) \) such that if \( v = (n_{ij}) \in A^{k(n+1)} \) and \( a_n = (\sum_{i=1}^{k} n_{i1} \alpha_i, \ldots, \sum_{i=1}^{k} n_{in+1} \alpha_i) \); then \( a \) is integral over \( a_n \) (i.e., \( a \subset \bar{a}_n \)) if and only if \( P_\alpha(\bar{n}_{ij}) \neq 0 \) for some \( \alpha \), where \( \bar{n}_{ij} \) denotes the image of \( n_{ij} \) in the residue field. (See [10], Sec. 5, Theorem 1.)

**Lemma 2.6.** Let \( A \) be a regular local ring of dimension \( n + 1 \) containing a field \( k \) of characteristic 0 which gets mapped onto the residue field of \( A \). Suppose \( D_i(1 \leq i \leq n + 1) \) is a system of \( k \)-derivations of \( A \) such that the induced maps \( D_i : \mathfrak{M}/\mathfrak{M}^2 \to A/\mathfrak{M} \) form a basis of the dual of \( \mathfrak{M}/\mathfrak{M}^2 \). Then if \( f \in \mathfrak{M} \) such that the ideal \( (D_1f, \ldots, D_{n+1}f) \) is primary for the maximal ideal, \( f \) belongs to the integral closure of \( (D_1f, \ldots, D_{n+1}f) \).

**Proof.** It suffices to show that if \( A \subset R \), where \( R \) is a discrete valuation ring, \( f \in \sum_{i=1}^{n+1} R \cdot D_i f \), we may further assume that the maximal ideal of \( A \) is contained in that of \( R \), since otherwise \( \sum_{i=1}^{n+1} R \cdot D_i f = R \) and the assertion is trivial. We may further suppose \( R \) complete. We can then find a subfield \( L \) of \( R \) such that \( L \supset k \) and \( R \) is the formal power series ring \( L[[T]] \) over \( L \) in some \( T \) generating the maximal ideal of \( R \). Let \( D \) denote the \( L \)-derivation \( d/dt \) of \( R \), so that clearly \( Rf \subset R \cdot Df \). It suffices to show that \( R \cdot Df \subset \sum_{i=1}^{n+1} R \cdot D_i f \). Let \( \text{Der}_k(A, R) \) be the \( R \)-module of \( k \)-derivations of \( A \) into \( R \) continuous for the \( \mathfrak{M} \)-adic topology, so that \( D|A \in \text{Der}_k(A, R) \). We will be done if we show that \( \text{Der}_k(A, R) \) is generated by the \( D_i(1 \leq i \leq n + 1) \) choose a basis \( x_i(1 \leq i \leq n + 1) \).
of $\mathfrak{m}$ such that $D_ix_j = \delta_{ij}(\text{mod} \mathfrak{m})$. The homomorphism $\text{Der}_k(A, R) \rightarrow R^{n+1}$ which sends $\bar{D}$ to $(\bar{D}x_1, \ldots, \bar{D}x_{n+1})$ is clearly injective. It is also surjective and the images of the $D_i$ generated $R^{n+1}$ by Nakayama, since it is so when we pass to the quotient modulo the maximal ideal of $R$. This proves the lemma.

Q.E.D.

We are now ready for the next corollary. For any $f \in C[z_1, \ldots, z_{n-1}]$ with an isolated singular point at (0), define

$$a_1(f) = \sum_{i=1}^{n+1} C\{z\} : \frac{\partial f}{\partial z_i} = \{Df/D \text{ a continuous } C \text{- derivation of } C\{z\}\},$$

$$a_2(f) = C\{z\}f + a_1(f),$$

$$a_3(f) = \overline{a_1(f)} = \text{integral closure of } a_1(f).$$

It follows from Lemma (2.6) that $a_1(f) \subset a_2(f) \subset a_3(f)$. Further, it is clear that for any $C$-automorphism $\varphi$ of $C\{z\}$, $a_i(\varphi(f)) = \varphi(a_i(f))$. Define the artinian local rings $A_i(f)$ by $A_i(f) = C\{z\}/a_i(f)$.

**Corollary 2.7.** Suppose $f, g \in C[z]$ and that for some $i(1 \leq i \leq 3)$ we are given an isomorphism over $C$, $\lambda : A_i(f) \cong A_i(g)$. Then the singularities of $f = 0$ and $g = 0$ at 0 are of the same type.

**Proof.** First we start with proving weaker statements. Suppose $a_1(f) \supset \mathfrak{m}^N$ and $g - f \in \mathfrak{m}^{N+2}$. Then $(\partial g/\partial z_i) - (\partial f/\partial z_i) \in \mathfrak{m}^{N+1} \subset \mathfrak{m}a_1(f)$, which shows that $a_1(f) = a_1(g)$. Hence for any $t$, if $h_t = tg + (1-t)f$, $a_1(f) = a_1(h_t)$, and it follows from the theorem that the singularities of $f$ and $g$ are of the same type. (Compare to [15].)

Next suppose $\varphi$ is a $C$-automorphism of $C\{z\}$ and $\varphi(f) = g$. We want to say that the singularities of $f$ and $g$ are of the same type. Let $J(\varphi)$ be the Jacobian matrix of $\varphi$, $\gamma(t)$ a smooth path in $\text{GL}(n+1, C)$ connecting $E$ to $J(\varphi)^{-1}$, and $\phi_t$ the automorphism of $C\{z\}$ induced by $\gamma(t)$. Applying the theorem to the family $h_t = \phi_t \circ \varphi(f)$, we see that we may assume $\varphi$ has Jacobian matrix the identity, so that we have $\varphi(z_i) = z_i + \psi_i(z)$, where $\psi_i$ begins with second degree terms. By what we said
at the beginning of the proof, if $\psi_i'$ denotes the power series obtained from $\psi_i$ by leaving out from $\psi_i$ all terms of degree $N$ ($N$ large) and $\varphi'$ the automorphism of $C\{z\}$ defined by $\varphi'(z_i) = z_i + \psi_i'(z)$, $\varphi(f) \equiv \varphi'(f)$ (mod $\mathfrak{M}^N$) so that $\varphi(f)$ and $\varphi'(f)$ have the same monodromy. Thus we may assume that the $\psi_i$ are polynomials. Now define an automorphism $\varphi$ of $C_tz_u$ by $\varphi t z i u \equiv t \psi i p z q$ and apply the theorem to $h_i = \varphi_t(f)$. Our assertion follows.

Suppose now that we have a $C$-isomorphism $\bar{\lambda} : A_i(f) \sim A_i(g)$. We can then find a $C$-automorphism $\lambda$ of $C_tz_u$ which makes the diagram

$\begin{array}{c}
C\{z\} \\
\downarrow \\
C\{z\}/a_i(f) \\
\downarrow \\
C\{z\}/a_i(g)
\end{array}
$

commutative, the vertical arrows being the natural maps. It follows that $\lambda(a_i(g)) = a_i(g)$. On the other hand, we have $\lambda(a_i(f)) = a_i(\lambda(f))$. Finally, since $a_i(f) = a_3(f)$, we deduce that $a_3(\lambda(f)) = a_3(g)$. But now, since the singularities of $f$ and $\lambda(f)$ are of the same type, we may assume that we have $a_3(f) = a_3(g)$. But now, there is a finite set $S \subset C$, $0 \notin S$, $1 \notin S$, such that for $t \in C - S$, the integral closure of the ideal $(t(\partial f/\partial z_i) + (1 - t)\partial g/\partial z_i)$ also equals $a_3(f)$. Join 0 and 1 in $C$ by a smooth path $\gamma(t)$ not containing any point of $S$, and apply the theorem to the family $h_t = \gamma(t) \cdot f + (1 - \gamma(t)) \cdot g$. Note that $\mu_t = \dim C C\{z\}/(\partial h_t/\partial z_i) = e(a_3(f))$ is constant. Q.E.D.

3 Plane Curve Case.

Let us show that our main theorem implies the conjecture 0.1 of the introduction when $n = 1$. Because of Zariski’s results in [19], it is sufficient to prove that the multiplicity $m_t$ of the curve $F(z_0, z_1, t) = 0$ of $C^2$ at 0 is independent of $t$.

But O. Zariski in [21] and M. Lejeune in [6] proved that:
**Theorem 3.1.** The topological type of a plane curve singularity at a singular point is determined by the topological type of each analytically irreductible component of this curve at the singular point and the intersection numbers of any pairs of distinct branches.

Then consider two plane curves defined by $f = 0$ and $g = 0$ and having an isolated singular point at 0. Suppose that these curves have the same topological type at 0. Then there is a one-to-one correspondence $\phi$ between their analytically irreductible branches, such that the branch $\gamma_i$ of $f = 0$ at 0 has the same topological type as the branch $\phi(\gamma_i)$ of $g = 0$ at 0. Thus, as the multiplicity at 0 is the sum of the multiplicities of each branch, it suffices to prove that the multiplicity is a topological invariant of an analytically irreductible plane curve at its singular point.

More generally using results of K. Brauner in [2], W. Burau in [3] and O. Zariski in [18] we have:

**Theorem 3.2.** Puiseux pairs (cf. [5]) of an analytically irreductible plane curve singularity depends only on the topology of the singularity.

If $(m_1, n_1), \ldots, (m_g, n_g)$ are the Puiseux pairs, one knowns that $n_1 \cdots n_g$ is the multiplicity of the singularity (cf. [5]).

On a Geometric Interpretation of Multiplicity

By C.P. Ramanujam (Madras)

The interpretation is as follows. Let \( Y \) be a projective variety of dimension \( n \), \( y \) a point of \( Y \), \( \mathcal{O} \) an ideal in the local ring \( \mathcal{O}_{Y,y} \) primary for the maximal ideal, and \( f : X \to Y \) a proper birational morphism of a non-singular variety \( X \) into \( Y \) such that \( \mathcal{O}_X \) is an invertible sheaf of ideals of \( X \). Then the multiplicity of \( \mathcal{O} \) in \( \mathcal{O}_{Y,y} \) equals \((-1)^{n-1}(D^n)\), where \( D \) is the effective divisor on \( X \) defined by \( \mathcal{O}_X \).

Following a suggestion by Bombieri, we present a generalisation of this result to sheaves of ideals defining closed subsets of arbitrary dimension. Also, we have given the result in the context of schemes.

All schemes considered will be noetherian and separated, and all morphisms considered separated of finite type.

First, we recall some basic facts on the blow-up of a scheme with respect to a coherent sheaf of ideals. (See [1].) Let \( Y \) be a scheme and \( \mathcal{I} \) a coherent sheaf of ideals in \( \mathcal{O}_Y \), defining a closed subscheme \( Z \) of \( Y \). Let \( \mathcal{R}(\mathcal{I}) \) be the quasi-coherent sheaf of graded \( \mathcal{O}_Y \)-algebras defined by

\[
\mathcal{R}(\mathcal{I}) = \mathcal{O}_Y \oplus \mathcal{I} \oplus \mathcal{I}^2 \oplus \ldots.
\]

Then the blow-up of \( Y \) with respect to \( \mathcal{I} \) or the blow-up of \( Z \) on \( Y \) is defined to be the \( Y \)-scheme \( X = \text{Proj} \mathcal{R}(\mathcal{I}) \). If \( Y \) is affine with \( \Gamma(Y, \mathcal{O}_Y) = A \) and \( \Gamma(Y, \mathcal{I}) = I \), \( X \) is covered by affine open sets isomorphic to \( \text{Spec} I \cdot f^{-1} \) where \( f \) runs through the elements (or even a set of generators) of \( I \) and \( I \cdot f^{-1} \) is the subring of the of quotients \( A_f = A[f^{-1}] \) consisting of elements of the form \( g/f^n \), \( g \in I^n \). If \( \varphi : X \to Y \) is the structural morphism, \( \mathcal{I} \mathcal{O}_X \) is an invertible sheaf of ideals of \( \mathcal{O}_X \) which is very ample for \( \varphi \), and the restriction of \( \varphi \) to \( \varphi^{-1}(Y - Z) \) is an isomorphism of this open subscheme onto \( Y - Z \). Further, if \( U \) is any non-void
open subset of $X$, it cannot happen that $\varphi(U) \subset Z$, since then $\mathcal{I} \cdot \mathcal{O}_U$ would be contained in the sheaf of nilpotents of $\mathcal{O}_U$ and hence cannot be invertible. Hence, if $Z$ contains no components of $Y$, or equivalently if $Y - Z$ is dense in $Y$, $\varphi$ maps an open dense subset of $X$ isomorphically onto an open dense subset of $Y$, i.e., $\varphi$ is birational.

Now, let $\psi : Y' \to Y$ be a morphism such that $\mathcal{I} \mathcal{O}_{Y'}$ is invertible. We assert that there is a unique morphism $\tilde{\psi} : Y' \to X$ such that $\varphi \circ \tilde{\psi} = \psi$. To prove this, we may clearly assume that $Y = \text{Spec} \ A$ and $Y' = \text{Spec} \ B$ are affine and that if $I = \Gamma(Y, \mathcal{I}), IB = f \cdot B$ for some $f \in I$, and also that the image of $f$ in $B$ is a non-zero divisor. Then $B \to B_f$ is injective, and under the induced homomorphism $A_f \to B_f$, the image of $I \cdot f^{-1}$ is contained in $B$. This proves the assertion. Finally, let $\xi$ be the generic point of a component of the closed subset of $Y'$ defined by $\mathcal{I} \mathcal{O}_{Y'}$, so that $\mathcal{O}_{\xi, Y'}$ is a local ring of dimension one. Since $(\mathcal{I} \mathcal{O}_{Y'})_{\xi}$ is a principal ideal generated by a non-zero divisor contained in the maximal ideal of $\mathcal{O}_{\xi, Y'}$, the maximal ideal of $\mathcal{O}_{\xi, Y'}$ is not associated to $(0)$. Hence if $\eta_1, \eta_2, \ldots, \eta_p$ are generic points of components of $Y'$ containing $\xi$, the natural homomorphism $\mathcal{O}_{\xi, Y'} \to \prod_{1}^{p} \mathcal{O}_{\eta_i, Y'}$ is injective.

Next we recall the definitions and some basic facts about the degree of an invertible sheaf. Let $m$ be an integer $\geq 0$, and $X$ a proper scheme over $\text{Spec} \ \Lambda$, where $\Lambda$ is an artinian ring, with $\dim X \leq m$. Then, if $\mathcal{L}$ is an invertible sheaf on $X$, and $\mathcal{I}$ any coherent sheaf on $X$,

$$P(n) = \sum_{i=0}^{n} (-1)^i l_\Lambda(H^i(X, \mathcal{I} \otimes \mathcal{L}^n))$$

is a polynomial in $n$ of degree $\leq m$. This is well-known when $\Lambda$ is a field (see for instance [2]), and the general case follows easily. The coefficient of $n^m$ in $\chi(\mathcal{L}^n)$ is of the form $\frac{d_m(\mathcal{L})}{m!}$, where $d_m(\mathcal{L})$ is an integer called the degree of $\mathcal{L}$ (the integer $m$ being fixed once for all). This has the following properties:

(i) If $X_i$ are the irreducible components of $X$ with reduced structure
and \( \mathcal{L}_i = \mathcal{L} \otimes_{\mathcal{O}_X} \mathcal{O}_{X_i} \) and \( \xi_i \) is the generic point of \( x_i \), we have

\[
d_m(\mathcal{L}) = \sum_i l(\mathcal{O}_{X, \xi_i}) d_m(\mathcal{L}_i).
\]

(ii) If \( f : Y \to X \) is a proper morphism, \( X \) irreducible and reduced of dimension \( m \) and \( \dim Y \leq m \), and if \( \xi \) is the generic point of \( X \),

\[
d_m(f^*(\mathcal{L})) = \left( \sum_{f(\eta) = \xi} \dim_{k(\xi)} \mathcal{O}_{Y, \eta} \right) \cdot d_m(\mathcal{L}).
\]

We can now state the main theorem.

**Theorem.** Let \( X \) be a noetherian scheme of dimension \( n \) and \( Y \) a closed subscheme of \( X \) defined by the coherent sheaf of ideals \( \mathcal{I} \). Suppose \( Y \) is a proper scheme over \( \text{Spec} \ \Lambda \) where \( \Lambda \) is an artinian ring. Suppose further that \( f : X' \to X \) is a proper birational morphism such that \( \mathcal{I} \mathcal{O}_{X'} \) is an invertible sheaf of ideals. Then we have:

(i) there exists a polynomial \( P(T) \) of degree \( \leq n - 1 \) such that for all large \( N \),

\[
P(N) = \sum_{i=0}^{n} (-1)^i l_{\Lambda}(H^i(X, \mathcal{I}^N / \mathcal{I}^{N+1})),
\]

(ii) the coefficient of \( T^{n-1} \) in \( P(T) \) is \( \frac{1}{(n-1)!} \cdot d_{n-1}(\mathcal{I} \mathcal{O}_{X'}) \).

**Proof.** Let \( g : \tilde{X} \to X \) be the blow-up of \( X \) with respect to the sheaf of ideals \( \mathcal{I} \). Then \( \mathcal{I} \mathcal{O}_{\tilde{X}} \) is an invertible sheaf relatively very ample for \( g \), hence \( \mathcal{I} \mathcal{O}_{\tilde{X}} / \mathcal{I}^2 \mathcal{O}_{\tilde{X}} \) is relatively very ample for the morphism \( g^{-1}(Y) = Y \times_X \tilde{X} \to Y \). It follows that for \( N \) large \( R^i g(\mathcal{I}^N \mathcal{O}_{\tilde{X}} / \mathcal{I}^{N+1} \mathcal{O}_{\tilde{X}}) = (0) \) for \( i > 0 \) and \( g_*(\mathcal{I}^N \mathcal{O}_{\tilde{X}} / \mathcal{I}^{N+1} \mathcal{O}_{\tilde{X}}) \cong \mathcal{I}^N / \mathcal{I}^{N+1} \). Hence from the Leray spectral sequence, for \( N \) large we have

\[
\sum_{i=0}^{n} (-1)^i l_{\Lambda}(H^i(X, \mathcal{I}^N / \mathcal{I}^{N+1})) = \sum_{i=0}^{n} (-1)^i l_{\Lambda}(H^i(Y \times_X \tilde{X}, \mathcal{I}^N \mathcal{O}_{\tilde{X}} / \mathcal{I}^{N+1} \mathcal{O}_{\tilde{X}}))
\]
and the right side is a polynomial of degree \( \leq \dim Y \times_X \bar{X} < \dim \bar{X} \leq n \) \((\Pi)\). This proves (i), and also (ii) for the special morphism \( g \).

Now, \( f \) factorises as \( g \circ h \) where \( h : X' \rightarrow \bar{X} \) is birational proper. We have to show that \( d_{n-1}(\mathcal{I} \mathcal{O}_{X'}) = d_{n-1}(\mathcal{I} \mathcal{O}_{\bar{X}}) \). Since \( \mathcal{I} \mathcal{O}_{\bar{X}} \) is an invertible sheaf of ideals, we have \( h^*(\mathcal{I} \mathcal{O}_{\bar{X}}) \approx \mathcal{I} \mathcal{O}_{X'} \). Put \( \bar{Y} = Y \times_X \bar{X}, Y' = Y \times_X X' \); in view of the preceding remarks, it suffices to show that if \( \eta \) is the generic point of an irreducible component of \( \bar{Y} \) of dimension \( n-1 \), we have

\[
l(\mathcal{O}_{\bar{Y},\eta}) = \sum_{\eta' \in Y' \atop h(\eta') = \eta} l(\mathcal{O}_{Y'_{\eta'},\eta'}).
\]

Set \( A = \mathcal{O}_{\bar{X},\eta} \). Then the morphism \( X' \times_X \text{Spec} A \rightarrow \text{Spec} A \) is proper with finite fibers, hence is a finite morphism. Thus, \( X' \times_X \text{Spec} A \) is isomorphic over \( \text{Spec} A \) to \( \text{Spec} B \) where \( B \) is an \( A \)-algebra which is a finite \( A \)-module. Let \( f \in A \) be a generator of \((\mathcal{I} \mathcal{O}_{\bar{X}})_\eta \). Then \( \mathcal{O}_{\bar{Y},\eta} \approx A/fA \) and

\[
\prod_{\eta' \in Y' \atop h(\eta') = \eta} \mathcal{O}_{Y'_{\eta'},\eta'} \approx B/fB.
\]

We have thus to show that \( l_A(A/fA) = l_A(B/fB) \). Assume for the moment that \( A \rightarrow B \) is injective and \( l_A(B/A) < \infty \). Then we have

\[
l_A(B/fA) = l_A(B/fB) + l_A(fB/fA) = l_A(B/A) + l_A(A/fA).
\]

But since \( f \) is a non-zero divisor in \( B \), multiplication by \( f \) induces an isomorphism \( B/A \approx fB/fA \) and \( l_A(B/A) = l_A(fB/fA) \). Inserting this in the above equality, the desired result follows.

To prove that \( A \rightarrow B \) is an injection and \( l_A(B/A) < \infty \), let \( K \) be the product of the (artinian) local rings of generic points of those components of \( X \) which contain \( \eta \) and \( L \) the product of the (artinian) local rings of generic points of those components of \( X \) which contain a point of \( h^{-1}(\eta) \). The natural homomorphisms \( A \rightarrow K \) and \( B \rightarrow L \) are injection in view of the remarks made earlier. Further, \( K \rightarrow L \) is an isomorphism since \( h \) is birational. Hence \( B \) can be identified with a finitely generated submodule of the total quotient ring \( K \) of \( A \). Hence there is a non-zero
On a Geometric Interpretation of Multiplicity

divisor $\lambda \in A$ such that $\lambda B \subset A$, and $B/A \cong \lambda B/\lambda A \hookrightarrow A/\lambda A$ which is of finite length over $A$.

The proof of the theorem is complete. $\square$

Remarks. (1) Suppose $A$ is a local ring of dimension $n \geq 1$ and $\mathcal{D}$ an ideal primary for the maximal ideal. The theorem is then applicable to $\text{Spec} A, Y$ the closed subscheme defined by $\mathcal{D}$ (and $\Lambda = A/\mathcal{D}$). The polynomial $P(N)$ then equals $l_{\lambda}(\mathcal{D}/N, \mathcal{D}/N+1)$ for $N$ large, and its leading coefficient is $\frac{1}{(n-1)!} e_{\mathcal{D}}(A)$, where $e_{\mathcal{D}}(A)$ is the multiplicity of $\mathcal{D}$.

Suppose now that $\mathcal{D}, \mathcal{D}'$ are two ideals primary for the maximal ideal and $g : X_1 \to X$ a proper birational morphism such that $\mathcal{D} \mathcal{O}_{X_1} = \mathcal{D}' \mathcal{O}_{X'}$. We can then find $h : X' \to X_1$ proper birational such that $\mathcal{D} \mathcal{O}_{X'} = \mathcal{D}' \mathcal{O}_{X'}$ is invertible. (Take for instance $X'$ to be the blow-up of $X_1$ with respect to $\mathcal{D} \mathcal{O}_{X_1}$.) It follows from the theorem applied to $g \circ h$ that $e_{\mathcal{D}}(A) = e'_{\mathcal{D}}(A)$. Now recall that if $\mathcal{D}' \supset \mathcal{D}, \mathcal{D}'$ is said to be integral over $\mathcal{D}$ if every $x$ in $\mathcal{D}'$ satisfies an equation $x^n + a_1 x^{n-1} + \cdots + a_n = 0$ with $a_i \in \mathcal{D}$. We assert that if $\mathcal{D}'$ is integral over $\mathcal{D}$, there is a $g : X_1 \to X$ proper birational such that $\mathcal{I} \mathcal{O}_{X_1} = \mathcal{I}' \mathcal{O}_{X_1}$. Infact, choose $X_1$ so that $\mathcal{D} \mathcal{O}_{X_1}$ and $\mathcal{D}' \mathcal{O}_{X_1}$ are both invertible. For any $x_1 \in X_1$, we have

$$\mathcal{D} \mathcal{O}_{X_1,x_1} = \lambda \mathcal{O}_{X_1,x_1} \subset \mathcal{D}' \mathcal{O}_{X_1,x_1} = \mu \mathcal{O}_{X_1,x_1}$$

with $\lambda, \mu \in \mathcal{D}_{X_1,x_1}, \lambda = \mu v, v \in \mathcal{O}_{X_1,x_1}$. Now $\mu$ must be integral over $\lambda \mathcal{O}_{X_1,x_1}$, hence satisfies an equation

$$\mu^m + a_1 \mu v \cdot \mu^{m-1} + a_2 (\mu v)^2 \mu^{m-2} + \cdots + a_m (\mu v)^m = 0, \quad a_i \in \mathcal{O}_{X_1,x_1},$$

i.e.,

$$\mu^m (1 + a_1 v + a_2 v^2 + \cdots + a_m v^m) = 0.$$

Since $\mu$ is not a zero divisor, it follows that $1 + v(a_1 + a_2 v + \cdots + a_m v^{m-1}) = 0$, and $v$ is a unit.

Thus, if $\mathcal{D}'$ is integral over $\mathcal{D}$, $e_{\mathcal{D}}(A) = e'_{\mathcal{D}}(A)$. This is a result due to Northcott and Rees ([4]).
(2) Let the assumptions be as in the theorem. Suppose further that 
$Y$ is a local complete intersection of codimension $r$ in $X$, i.e., 
suppose for every $y \in Y$, $\mathcal{I}_y$ is generated by an $\mathcal{O}_{X,Y}$-sequence 
of length $r$. Then $\mathcal{I}/\mathcal{I}^2$ is locally free of rank $r$ on $Y$ and 
$\bigoplus_{m \geq 0} \mathcal{I}^m/\mathcal{I}^{m+1}$ is isomorphic to the symmetric algebra $S(\mathcal{I}/\mathcal{I}^2)$ 
over $\mathcal{O}_Y$ (see [5]). Then $\chi(\mathcal{I}^N/\mathcal{I}^{N+1}) = P(N)$ where $P$ is a polynomial, 
for all $N \geq 0$.

Now, suppose further that a theory of Chern classes is defined on 
$Y$ with values in a graded ring $A(Y)$ with the usual properties. (For in-
stance, $\Lambda = \mathbb{C}$, $Y$ reduced and $A(Y)$ the even dimensional integral 
cohomology of $Y$; or $\Lambda$ an algebraically closed field, $Y$ non-singular 
projective over $\Lambda$ and $A(Y)$ the Chow ring of rational equivalence; or 
any $\Lambda$, and $A(Y)$ is the associated graded ring of $K(Y)$ with respect to 
the $\lambda$-filtration, tensored with $\mathbb{Q}$.) Since $\dim Y \leq n - r$, we have a homo-
morphism $A^{n-r}(Y) \to \mathbb{Q}$ which we denote by $\xi \mapsto \xi[Y]$. There is then a 
universal polynomial $Q$ (depending only on $n$ and $r$) in the Chern classes 
$c_i$ of $\mathcal{I}/\mathcal{I}^2$ such that the coefficient of $N^{n-1}$ in $P(N)$ equals $Q(c_i)[Y]$.

These are general assertions having to do with a locally free sheaf $\xi$ 
($(\mathcal{I}/\mathcal{I}^2)$ in our case) of rank $r$ and its symmetric powers on a scheme $Y$ 
of dimension $m$ proper over Spec $\Lambda$, $\Lambda$ an artinian ring. To prove them, 
let $\mathbb{P}(\xi^*)$ be the projective bundle associated to the dual sheaf $\xi^*$ on $Y$, 
and $\mathcal{O}(1)$ the canonical invertible sheaf on $\mathbb{P}(\xi^*)$. If $\pi : \mathbb{P}(\xi^*) \to Y$ is 
the projection, we have $R^i\pi_*(\mathcal{O}(N)) = (0), i > 0, N \geq 0$ and $\pi_*(\mathcal{O}(N)) \approx 
S^N(\xi)$. Hence by the Leray spectral sequence, $\chi(Y, S^N(\xi)) = \chi(\mathbb{P}(\xi^*), 
\mathcal{O}(N))$, which shows that $\chi(Y, S^N(\xi))$ is a polynomial in $N$. Further, if $\xi$ 
is the first Chern class of $\mathcal{O}(1)$ on $\mathbb{P}(\xi^*)$, the coefficient of $N^{r+m-1}$ in this 
polynomial is $\frac{1}{(r + m - 1)!} \xi^{r+m-1}[\mathbb{P}(\xi^*)]$. Now, $\xi$ satisfies an equation 
$\xi^r - c_1\xi^{r-1} + \cdots \pm c_r = 0$, where $c_i$ are the Chern classes of $\mathcal{E}$ and 
$A(\mathbb{P}(\xi^*))$ is considered as an $A(Y)$-algebra via $\pi$. Dividing $\xi^{r+m-1}$ by 
$\xi^r - c_1\xi^{r-1} + \cdots \pm c_r$ leaves a remainder 

$$\alpha_0 + \alpha_1 \xi + \cdots + \alpha_{r-1} \xi^{r-1}$$

where the $\alpha_i$ are universal polynomials in $c_1, \ldots, c_r$. Further, by the
projection formula, \( \alpha_i \xi^i [\mathbb{P}(E^*)] = 0 \) for \( i < r - 1 \) and \( \alpha_{r-1} \xi^{r-1} [\mathbb{P}(E^*)] = \alpha_{r-1} [Y] \). Thus, we may take \( Q = \frac{1}{(r + m - 1)} \alpha_{r-1} \).

Supplement to the Article “Remarks on the Kodaira Vanishing Theorem”

By C.P. Ramanujam*

Received August 24, 1973

Throughout this Paper, we work over an algebraically closed field of characteristic zero, which we may assume is the field of complex numbers. We adhere to the notations of the paper referred to in the title.

Our first remark was pointed out to us by E. Bombieri, and is used by him in his investigations of pluri-canonical surfaces.

If $X$ is a complete non-singular surface and $D$ an effective divisor on $X$ with $(D^2) > 0$, then

$$H^1(X, O_X) \rightarrow H^1(D, O_D)$$

is injective.

Proof. By the Riemann-Roch theorem, $\dim H^0(X, O_X(nD))$ increases quadratically in $n$. Hence for some $n > 0$, if $F$ is the divisor of base components of $|nD|$, $|nD| - F$ is a linear system without base components not composite with a pencil. We then have, in the terminology of Lemma 6 of (2),

$$\alpha(D) = \alpha(nD) \leq \alpha(nD - F) = 0$$

by Theorem 2 and Lemma 6 of (2).

Our next result is the following

\[ \Box \]

Theorem. Let $X$ be a complete non-singular surface and $\mathcal{L}$ an invertible sheaf on $X$ such that $(c_1(\mathcal{L})^2) > 0$ and $(c_1(\mathcal{L}) \cdot C) \geq 0$ for any curve $C$ on $X$. Then $H^i(X, \mathcal{L}^{-1}) = 0$, $i = 0, 1$.

Conversely, if $(c_1(\mathcal{L})^2) > 0$ and $H^i(X, \mathcal{L}^{-n}) = 0$, $i = 1, 2$ and $n$ large, for any curve $C$ on $X$, $(c_1(\mathcal{L}) \cdot C) \geq 0$.

Proof. We first prove the sufficiency of the condition.

Suppose first that $H^0(X, \mathcal{L}) \neq 0$, so that $\mathcal{L} \cong \mathcal{O}_X(D)$, $D$ an effective divisor. We show that $D$ is numerically connected. Suppose on the contrary that $D = D_1 + D_2$, $D_i$ effective, $(D_1 \cdot D_2) = -\lambda \leq 0$. Since $(D_1^2) = (D_1 \cdot D_2) = (D \cdot D_1) \geq 0$ by assumption, $(D_1^2) \geq \lambda$ and similarly $(D_2^2) \geq \lambda$. Now, if $D_1$ and $D_2$ are linearly dependent modulo numerical equivalence, we must have $aD_1$ numerically equivalent to $bD_2$ where $a$ and $b$ are positive integers, since $D_i$ are effective. But then, since $(D_2^2) > 0$, $(D_1 \cdot D_2) > 0$. Thus, $D_i$ are independent modulo numerical equivalence, and by the Hodge index theorem,

$$\det \begin{pmatrix} (D_1^2) & -\lambda \\ -\lambda & (D_2^2) \end{pmatrix} = (D_1^2)(D_2^2) - \lambda^2 < 0,$$

which is a contradiction. Thus, $D$ is numerically connected. But now, the assertion follows from our earlier remark, Lemma 3 of (2) and the exact sequence

$$H^0(X, \mathcal{O}_X) \to H^0(D, \mathcal{O}_D) \to H^1(X, \mathcal{L}^{-1}) \to H^1(X, \mathcal{O}_X) \to H^1(D, \mathcal{O}_D).$$

Next, consider the case when $\mathcal{L}$ does not admit a non-zero section. Our hypotheses clearly imply that for $H$ ample, $(c_1(\mathcal{L}) \cdot H) > 0$, and hence $H^0(X, \Omega_X^2 \otimes \mathcal{L}^{-n}) = 0$ for $n$ large. Hence, by Riemann-Roch, there is an $n > 0$ such that $\mathcal{L}^n$ admits a non-zero section $\sigma$ with $\text{div} \sigma = D$. By Lemma 1 of (2) and the theorem of resolution of singularities, we can find a complete non-singular surface $Y$ and a surjective morphism $f : Y \to X$ such that $f^*(\mathcal{L})$ admits a section $\tau$ with $\tau^n = f^*(\sigma)$ in $f^*(\mathcal{L}^n)$. For any curve $C'$ on $Y$, we have

$$(c_1(f^*(\mathcal{L})) \cdot C') = (f^*(c_1(\mathcal{L})) \cdot C') = (c_1(\mathcal{L}) \cdot f^*(C')) \geq 0,$$
so that $f^*(\mathcal{L})$ on $Y$ satisfies the hypothesis and also admits a non-zero section. Hence, by the first part and Serre duality,

$$H^i(Y, \Omega_Y^2 \otimes f^*(\mathcal{L})) = 0, \ i > 0.$$ 

Now, by Lemma 4 of (2) and Stein factorisation,

$$R^i f(\Omega_Y^2) = 0, \ i > 0.$$ 

Thus, by the Leray spectral sequence,

$$H^i(X, f_* (\Omega_Y^2) \otimes \mathcal{L}) = 0, \ i > 0.$$ 

We have a splitting $1/m \ Tr : f_* (\Omega_Y^2) \to \Omega_X^2 (m = \deg f)$ of the natural homomorphism $\Omega_X^2 \to f_* (\Omega_Y^2)$ (See footnote on p.44 of (2)), which gives

$$H^i(X, \Omega_X^2 \otimes \mathcal{L}) = 0, \ i > 0,$$

and the result follows by Serre duality.

We next prove the converse part of the theorem. If $H$ is ample, $(H \cdot c_1(\mathcal{L})) \neq 0$, by the Hodge index theorem. By our hypothesis and Riemann-Roch, $H^0(X, \Omega_X^2 \otimes \mathcal{L}^n) \neq 0$ for $n$ large, so that $(H \cdot (K + nc_1(\mathcal{L}))) > 0$ for $n$ large. Hence $(H \cdot c_1(\mathcal{L})) > 0$ and $H^0(K \otimes \mathcal{L}^{-n}) = 0$ for $n$ large. Hence $(H \cdot c_1(\mathcal{L})) > 0$ and $H^0(K \otimes \mathcal{L}^{-n}) = 0$ for $n$ large. Again by Riemann-Roch, $H^0(\mathcal{L}^n) \neq 0$ for some $n > 0$, and replacing $\mathcal{L}$ by $\mathcal{L}^n$, we may assume $H^0(\mathcal{L}) \neq 0, \mathcal{L} \simeq O_X(D)$ for some effective divisor $D$.

From the cohomology exact sequence of the short exact sequence

$$0 \to O_X(-(n + 1)D) \xrightarrow{D} O_X(-nD) \to O_D \otimes O_X(-nD) \to 0$$

we deduce that $H^0(O_D \otimes O_X(-nD)) = 0$ for $n$ large. We can clearly find a morphism $f : \tilde{D} \to D$ such that (i) $f$ is finite, (ii) every connected component of $\tilde{D}$ is irreducible, and (iii) there is a finite set $S$ of points on $D$ such that $f|f^{-1}(D - S)$ in an isomorphism onto $D - S$. We then have an exact sequence

$$0 \to O_D \to f_* (O_{\tilde{D}}) \to \mathcal{F} \to 0$$
where $\mathcal{F}$ is a sheaf supported at finitely many points. We deduce from this that

$$\dim H^0(\tilde{D}, f^*(\mathcal{O}_X(-nD))) = \dim H^0(D, f_*(\mathcal{O}_D) \otimes \mathcal{O}_X(-nD))$$

is bounded. Hence for any component $C$ of $D$, we must have $(D \cdot C) \geq 0$. But for a curve $C'$ which is not a component of $D$, the inequality $(D \cdot C') \geq 0$ is obviously satisfied. Q.E.D.

\[\square\]

**Remarks.** (1) Using the Lemma of Enriques-Severi-Zariski-Serre as in the proof of Theorem 2 of (2), it is easy to deduce from the above theorem the following generalisation to higher dimensional varieties:

If $X$ non-singular projective of dimension $n$ and $\mathcal{L}$ an invertible sheaf on $X$ with $(c_1(\mathcal{L})^n) > 0$ and $(c_1(\mathcal{L}) \cdot C) \geq 0$ for any curve $C$ on $X$, then $H^1(X, \mathcal{L}^{-1}) = 0$.

(2) The assumptions that $D$ effective, $(D^2) > 0$ and $(D \cdot C) \geq 0$ do not imply that $|nD|$ has no base components for some $n > 0$, as is shown by the following example:

Let $C$ be an elliptic curve, and $X$ the projective line bundle on $C$ obtained by compactifying a line bundle $\mathcal{L}$ of degree-1 on $C$ by adding points at infinity to the fibers. Let $D_1$ be the zero section and $F$ the fiber over a point $P$ of $C$. Then,

$$((D_1 + F)^2) = (D_1^2) + 2(D_1 \cdot F) = -1 + 2 = 1.$$ 

If $C$ is a curve not a component of $D_1 + F$, we have evidently $(C \cdot (D_1 + F)) > 0$. On the other hand, $((D_1 + F) \cdot F) = 1$ and $((D_1 + F) \cdot D_1) = (D_1^2) + (D_1 \cdot F) = -1 + 1 = 0$. If some linear system $|n(D_1 + F)|$ does not have $D_1$ for a base curve, we deduce that $\mathcal{O}_{D_1} \otimes \mathcal{O}_X(n(D_1 + F))$ is trivial on $D_1$, i.e., $\mathcal{L}^n \otimes \mathcal{O}_C(nP)$ is trivial on $C$. But we can choose $P$ such that $\mathcal{L} \otimes \mathcal{O}_C(P)$ is not of finite order. Then $D_1$ is a base component of each of the linear systems $|n(D_1 + F)|$.

Our theorem is therefore strictly stronger than Theorem 2 of (2).

Appendix

By C.P. Ramanujam

The proof of Prop. 3 has been essentially global. The following result gives a “local proof” of Prop. 3.

Proposition. Let $A$ be a noetherian analytically normal local ring with maximal ideal $\mathfrak{m}$. Let $B$ be a noetherian local ring with maximal ideal $\mathfrak{n}$ such that $B$ contains $A$ and has the same residue field as $A$. Let us suppose that $\mathfrak{n} \cap A = \mathfrak{m}$ and that $\mathfrak{n}$ is generated by $\mathfrak{m}$ together with elements $x_1, \ldots, x_r$ of $B$, where $r = \dim B - \dim A$.

Then any prime ideal $\mathfrak{p}$ of height one in $B$ which is not contained in $\mathfrak{m} \cdot B$ is principal.

Proof. Let $A$ and $B$ be the completions of $A$ and $B$ respectively. The hypothesis that $\mathfrak{n}$ is generated by $\mathfrak{m}$ together with $r = \dim B - \dim A$ elements on $\mathfrak{n}$ implies that $B$ is isomorphic to the formal power series ring $A \left[ [X_1, \ldots, X_r] \right]$ in $r$ variables over $A$, as can be shown easily. Since $\mathfrak{p}$ is of height one in $B$, there exist elements $a, b \in B$ such that $(a : b) = \mathfrak{p}$, and hence by a well-known property of completions ($B$ is $B$ flat), we deduce that $(aB : bB) = \mathfrak{p}B = \mathfrak{p}$, which implies in turn (since $\hat{B}$ is normal) that all the associated prime ideals of $\mathfrak{p}B$ in $B$ are of height one. Moreover, since $\mathfrak{p} \not\subseteq \mathfrak{m} \cdot B$, $\mathfrak{p} \not\subseteq \mathfrak{m} \cdot B = \mathfrak{m} \cdot B$, and the same holds for all the associated prime ideals of $\mathfrak{p}$. If we could prove that each of these associated prime ideals is principal, it would then follow that $\mathfrak{p}B$ is principal, and hence that $\mathfrak{p}$ is principal (since $B$ is $B$-flat).

*This proposition could be used to prove straightaway that the Weil divisor $C$ in Prop. 4 is a divisor; thereby one could avoid going to the variety $Z$ for the proof of Prop. 4.
Thus, it is enough to prove the theorem when $A$ is a complete normal local domain, and $B$ a formal power series ring $A[[X_1, \ldots, X_r]]$ in $r$ variables over $A$. □

We shall do this in a series of lemmas.

**Lemma 1.** Let $A$ be a local ring with maximal ideal $m$, and $f$ an element of $A[[X_1, \ldots, X_p]]$ which does not lie in the ideal $mA[[X_1, \ldots, X_p]]$. Then there is an automorphism $\varphi$ of $A[[X_1, \ldots, X_p]]$ which fixes $A$ such that $\varphi(f) \notin (m, X_1, \ldots, X_{p-1})$.

**Proof.** The proposition being trivial for $p = 1$, we may assume that $p \geq 2$. We proceed by induction on $p$.

Let $p = 2$ and $f = \sum_{r,s} a_{r,s}X_1^rX_2^s$, and let $a_{r_0,s_0}$ be a coefficient which is not in $m$. We may assume that $r_0$ is minimal with this property. Let $N$ be any integer greater than $s_0$, and define

$$
\varphi(X_1) = X_1 + X_2^N
$$

$$
\varphi(X_2) = X_2.
$$

Then $\varphi$ extends to a unique automorphism of $A[[X_1, X_2]]$, which fixes $A$, by continuity. The coefficient of $X_2^{r_0N+s_0}$ in $\varphi(f)$ is the sum of the $a_{r,s}$ for which $rN + s = r_0N + s_0$. This implies that $N$ divides $s - s_0$, and since $s$ and $s_0$ are non-negative and $N > s_0$, that $s \geq s_0$, and $r \leq r_0$. By the minimality of $r_0$, we see that those $a_{r,s}$ which occur in the sum with $(r, s) \neq (r_0, s_0)$ are in $m$, and since $a_{r_0,s_0} \notin m$, the coefficient of $X_2^{r_0N+s_0}$ in $\varphi(f)$ is not in $m$.

Now let $p$ be any integer $> 2$ and assume that the lemma is valid for $p - 1$ variables. Writing $f = \sum_{q=0} f_qX_p^q$, with $f_q \in A[[x_1, \ldots, X_{p-1}]]$, we see that there is an $f_{q_0} \notin mA[[X_1, \ldots, X_{p-1}]]$, and by induction hypothesis, there is an automorphism $\varphi'$ of $A[[X_1, \ldots, X_{p-1}]]$ such that $\varphi'(f_{q_0}) \notin (m, X_1, \ldots, X_{p-2})$. Extending $\varphi'$ to $A[[X_1, \ldots, X_p]]$ by putting $\varphi'(X_p) = X_p$ (and continuity), we see that $\varphi'(f) \in A[[X_1, \ldots, X_{p-2}]][[X_{p-1}, X_p]]$ and $\varphi'(f) \notin (m, X_1, \ldots, X_{p-2})$. Since we have proved the lemma for $p =$
2, there is an automorphism $\varphi''$ of $A \left[ X_1, \ldots, X_p \right]$ such that $\varphi''(\varphi'(f)) \notin (m, X_1, \ldots, X_{p-2}, X_{p-1})$, and $\varphi = \varphi'' \circ \varphi'$ fulfills the requirements. \hfill \Box

Lemma 1 clearly reduces the proof of the proposition to the case when $B = A[[X]]$ and $A$ are before. We shall assume this from now on.

**Lemma 2.** Let $A$ be a complete local ring with maximal ideal $m$ and $f \in A[[X]], f \notin m[[X]]$. Let $r$ be the least integer such that $f_r \notin m \left( f = \sum_0^\infty f_rX^r \right)$. If $g \in A[[X]]$ there exists a unique $h \in A[[X]]$ such that

$$g = hf + R,$$

$$R = \sum_0^{r-1} r_iX^i,$$

In particular, $f$ is the associate of a unique polynomial $X^r + \alpha_1X^{r-1} + \ldots + \alpha_r, \alpha_i \in m$.

**Proof.** The proof of the Weierstrass preparation theorem as given in Zariski and Samuel (Vol. II, Commutative Algebra, p. 139) carries over almost word for word. \hfill \Box

**Lemma 3.** $A$ is as in Lemma 2 a an ideal of $A [[X]], \alpha \notin m[[X]]$. Then $\alpha$ is generated by $\alpha \cap A[X]$.

**Proof.** Let $f$ be any element of $\alpha$ which is not in $m[[X]]$, and $r$ as in Lemma 1. If $g$ is any element of $\alpha$, it follows from Lemma 1 that $g = hf + R, R \in A[X]$, and $f$ is the associate of an element of $A[X]$. Lemma 3 is proved.

We can now complete the proof of the proposition. By Lemma 3 it is enough to show that $p \cap A[X] = p_1$, is a principal ideal of $A[X]$. Let $S$ be the set of non-zero elements of $A$; then $A[X]_S = Q[X], Q$ being the quotient field of $A$. We assert that $S \cap p_1 = \emptyset$. In fact, if $\alpha \in p_1 \cap S$, $p_1$ (being of height one) must be associated to $\alpha A[X]$. But since $\alpha \in A$, the associated prime ideals of $\alpha$ in $A[X]$ are all the extensions to $A[X]$ of the
prime ideals associated to $\alpha$ in $A$, and all these extensions are $\subset m[X]$. This contradicts the fact that $p_1 \not\subset m[X]$.

It follows that $p_1Q[X]$ is a prime ideal of $Q[X]$. Let $f = X^n + a_1X^{n-1} + \cdots + a_n, a_i \in Q$ be the monic polynomial which generates $p_1Q[X]$. We assert that $a_i \in A$. In fact, let $\bar{X}$ be the image of $X$ in $Q[X]/p_1Q[X] = Q[\bar{X}]$. Since $p \not\subset m[[X]]$, it follows from Lemma 2 that there is a monic polynomial over $A[X]$ which is in $p$, and hence in $p_1$, this proves that $\bar{X}$ is integral over $A$. But since $A$ is integrally closed, the minimal polynomial of $\bar{X}$ over $Q$, i.e., $f$, must be in $A[X]$, and our assertion is proved. But now, since $p_1$ is prime, we must have $p_1Q[X] \cap A[X] = p_1(A[X])_S \cap A[X] = p_1$, and $f \in p_1$. Since $f$ is monic, and divides any element of $p_1$ in $Q[X]$, it does so in $A[X]$.

Our result is proved.

*Added in proof.* The proposition in the Appendix has been proved in a special case by P. Samuel (Sur une conjecture de Grothendieck, Comptes Rendus, Paris, Tome 255).

Appendix I
The Theorem of Tate

By C. P. Ramanujam

We have seen that if $X$ and $Y$ are abelian varieties over a field $k$ (algebraically closed) and $l$ a prime different from the characteristic of $k$, the natural homomorphism

$$\mathbb{Z}_l \otimes_{\mathbb{Z}} \text{Hom}(X, Y) \xrightarrow{T_1} \text{Hom}_{\mathbb{Z}_l}(T_l(X), T_l(Y))$$

(1)

is injective. It is obviously of importance to know the image.

By a field of definition of $X$, we shall mean a subfield $k_0$ of $k$ over which there is a group scheme $X_0$ and an isomorphism of group schemes $X_0 \otimes_{k_0} k \to X$. We also say that $X$ is an abelian variety defined over $k_0$. Now choose a common field of definition $k_0$ for $X$ and $Y$; we may and shall assume $k_0$ to be of finite type over the prime field. Let $\overline{k}_0$ be the algebraic closure of $k_0$ in $k$. Since $n_X$ and $n_Y (n \in \mathbb{Z})$ are morphisms defined over $k_0$, their respective kernels $X_n$ and $Y_n$ consist entirely of $\overline{k}_0$-rational points, or in other words, the points of finite order in $X$ and $Y$ are $\overline{k}_0$-rational (i.e., they come from $\overline{k}_0$-rational points of $X_0 \otimes_{k_0} \overline{k}_0$ and $Y_0 \otimes_{k_0} \overline{k}_0$ resp.) Thus, if $G = G(\overline{k}_0/k_0)$ is the Galois group of $k_0$ over $k_0$, $G$ acts on the groups $X_n$ and $Y_n$ compatible with the homomorphisms $X_{mn} \to X_n$ and $Y_{mn} \to Y_n$. Hence $G$ acts continuously on the $\mathbb{Z}_l$-modules $T_l(X)$ and $T_l(Y)$, where we give $G$ the Krull topology and $T_l(X)$ and $T_l(Y)$ their $l$-adic topologies.

Furthermore, let $\varphi$ be any homomorphism of $X$ into $Y$. Since the points of finite order in $X$ are $\overline{k}_0$-rational and $k$-dense, and $\varphi$ maps points of finite order into points of finite order, $\varphi$ is defined over $\overline{k}_0$ and hence over a finite extension $k_1$ of $k_0$ in $\overline{k}_0$ (i.e., comes by base extension from
a homomorphism of group schemes $X_0 \otimes_{k_0} k_1 \to Y_0 \otimes_{k_0} k_1$). It then follows that if $H = G(\bar{k}_0/k_1) \subset G$ is the subgroup of $G$ fixing $k_1$, for any $\bar{k}_0$-rational point $x$ of $X$, we have $h\varphi(x) = \varphi(hx)$ for all $h \in H$. Thus, if we make $G$ act on $\text{Hom}_{\mathbb{Z}}(T_{l}(X), T_{l}(Y))$ by putting $(g\lambda)(x) = g(\lambda(g^{-1}x))$ for $g \in G$, $\lambda \in \text{Hom}_{\mathbb{Z}}(T_{l}(X), T_{l}(Y))$ and $x \in T_{l}(X)$, we see that $hT_{l}(\varphi) = T_{l}(\varphi)$ for $h \in H$. In other words, for any $\varphi \in \text{Hom}(X, Y)$, there is a neighborhood $H$ of the identity in $G$ fixing $T_{l}(\varphi)$. We see therefore that if for any $G$-module $M$ we denote by $M^{(G)}$ the subgroup of elements fixed by some neighborhood of $e$, the image of (1) is contained in $\text{Hom}_{\mathbb{Z}}(T_{l}(X), T_{l}(Y))^{(G)}$, and we obtain a homomorphism

$$\mathbb{Z}_l \otimes_{\mathbb{Z}} \text{Hom}(X, Y) \to \text{Hom}_{\mathbb{Z}}(T_{l}(X), T_{l}(Y))^{(G)}. \tag{2}$$

Tate conjectures that (2) is an isomorphism (or equivalently (2) is surjective) for any field of definition $k_0$ of finite type over the prime field. He proves this for abelian varieties defined over a finite field. It has also been proved when $k_0$ is an algebraic number field and $X = Y$ is of dimension one (Serre). We shall now reproduce Tate’s proof in the case of finite fields.

**Theorem 1.** Let $X$ and $Y$ be abelian varieties defined over a finite field $k_0$. Then the homomorphism (2) is an isomorphism.

The rest of this section will be devoted to the proof, which we give in several steps.

**Step I.** It suffices to show that the homomorphism

$$\mathbb{Q}_l \otimes_{\mathbb{Z}} \text{Hom}(X, Y) = \mathbb{Q}_l \otimes_{\mathbb{Q}} \text{Hom}^0(X, Y) \to \text{Hom}_{\mathbb{Q}}(V_{l}(X), V_{l}(Y))^{(G)} \tag{3}$$

where $V_{l}(X) = \mathbb{Q}_l \otimes_{\mathbb{Z}_l} T_{l}(X)$, is bijective.

In fact, if this were so, the image of the homomorphism (1) would be a $\mathbb{Z}_l$-submodule of maximal rank in $\text{Hom}_{\mathbb{Z}}(T_{l}(X), T_{l}(X))^{(G)}$. On the other hand, if this image is $M$, $\text{Hom}_{\mathbb{Z}}(T_{l}(X), T_{l}(X))/M$ has no torsion; for, suppose $\varphi \in \text{Hom}_{\mathbb{Z}}(T_{l}(X), T_{l}(X))$ and $l_{\varphi} \in M$. We can find $\psi_n \in$
Appendix I - The Theorem of Tate

Hom(X, Y) such that \( T_I(\psi_n) \to l_\varphi \), so that for all large n, \( T_I(\psi_n) = l_{\varphi_n \varphi_n} \in \text{Hom}_{\mathbb{Z}_l}(T_I(X), T_I(Y)) \). Thus, \( T_I(\psi_n)(T_I(X)) \subset lT_I(Y) \) and \( \psi_n \) vanishes on \( X_I \). Thus \( \psi_n \) admits a factorisation \( \psi_n = \chi_n \circ l_X = l\chi_n \) and the \( \chi_n \) converge to a certain \( \chi \) in \( \mathbb{Z}_l \otimes \mathbb{Z} \text{Hom}(X, Y) \) with \( T_I(\chi) = \varphi \), so that \( \varphi \in M \). This proves our assertion, and establishes that \( M = \text{Hom}_{\mathbb{Z}_l}(T_I(X), T_I(Y))^{(G)} \).

**Step II.** It suffices to show that for any abelian variety \( X \) defined over a finite field

\[
Q_l \otimes \text{End}^0(X) \xrightarrow{\lambda} \text{End}_{Q_l}(V_l(X))^{(G)}
\]

is an isomorphism.

In fact, if (4) is an isomorphism with \( X \times Y \) instead of \( X \), since we have the direct sum decompositions as \( G \)-modules

\[
\begin{align*}
Q_l \otimes \text{End}^0(X \times Y) &\xrightarrow{\sim} (Q_l \otimes \text{End}^0 X) \oplus (Q_l \otimes \text{End}^0 Y) \oplus (Q_l \otimes \text{Hom}^0(X, Y)) \oplus (Q_l \otimes \text{Hom}^0(Y, X)) \\
\text{End}(V_l(X \times Y)) &\xleftarrow{\sim} \text{End}(V_l(X)) \oplus \text{End}(V_l(Y)) \oplus \text{Hom}(V_l(X), V_l(Y)) \oplus \text{Hom}(V_l(Y), V_l(X)),
\end{align*}
\]

the above diagram is commutative and the first vertical arrow is an isomorphism, (3) is an isomorphism.

Thus, henceforward we shall restrict ourselves to a single abelian variety \( X \) defined over a finite field, and prove that (4) is an isomorphism.

**Step III.** It suffices to show that \( \lambda \) is an isomorphism for one \( l \) and that \( \dim Q_l \text{End}(V_l(X))^{(G)} \) is independent of \( l \neq \text{char. } k \).

This follows from the fact that the dimension of the left member in (4) is independent of \( l \) and \( \lambda \) is always injective.

**Step IV.** To establish (4) for an \( l \), it suffices to show the following. Let \( E \) be the image of \( \lambda \), and \( F \) the intersection over all neighborhoods of \( e \) in \( G \) of the subalgebras generated in \( \text{End}_{Q_l}(V_l) \) by these neighborhoods. Then \( F \) is the commutant of \( E \) in \( \text{End}(V_l) \).

In fact, since \( E \) is semi-simple, if the above were true, it would follow from von Neumann’s density theorem that \( E \) is the commutant of \( F \). Further, since \( \text{End}_{Q_l}(V_l) \) is of finite dimension over \( Q_l \), \( F \) actually
equals the subalgebra generated by some neighborhood, and all smaller
neighborhoods generate the same subalgebra. Hence the commutant of
$F$ is precisely $\text{End}_Q(V_I)^{(G)}$.

Now, Steps II-IV are valid for any field of definition $k_0$, and do not
make use of the fact that $k_0$ is finite. The next step makes use of a certain
hypothesis which is easily seen to be true for finite fields, and probably
holds for any field of finite type over its prime field. We therefore state
it as a hypothesis, verify it for a finite field and deduce its consequences.

Let $X$ be an abelian variety defined over a field $k_0$, $l$ a prime. We
then state the

**Hypothesis ($k_0, X, l$):** Let $d$ be any integer $\geq 1$. Then there exist
upto isomorphism only a finite number of abelian varieties $Y$ defined
over $k_0$, such that:

(a) there is an ample line bundle $L$ on $Y$ defined over $k_0$ with $\chi(L) = d$;

(b) there exists a $k_0$-isogeny $Y \to X$ of $l$-power degree.

(If $X \cong X_0 \otimes_{k_0} k$ and $Y \cong Y_0 \otimes_{k_0} k$, a line bundle $L$ on $Y$ is said to be
defined over $k_0$ if there is a line bundle $L_0$ on $Y_0$ such that $L \cong L_0 \otimes_{k_0} k$,
and an isogeny $Y \to X$ is said to be defined over $k_0$ if it arises from a
homomorphism $Y_0 \to X_0$ by base extension to $k$.)

For finite fields $k_0$, we have in fact the following stronger

**Lemma 1.** If $k_0$ is a finite field, $d > 0$ and $g > 0$, there are upto isomor-
phism only finitely many abelian varieties $Y$ defined over $k_0$ of dimension
g and carrying an ample line bundle $L$ defined over $k_0$ with $\chi(L) = d$.

**Proof.** The line bundle $L^3$ on $Y$ is defined over $k_0$ and gives a projective
embedding of $Y$ as a $k_0$-closed subvariety of projective space of dimension
$3^g \chi(L) - 1 = 3^g d - 1$. The degree of this subvariety is the $g$-fold
self intersection number of $L^3$, that is, $3^g \cdot (L)^g \cdot d = 3^g \cdot g! d$. Thus, there
corresponds to it a $k_0$-rational point of the Chow variety of cycles of di-

mension $g$ and degree $3^g \cdot g! d$ in $\mathbb{P}^{3^g d - 1}$. Since $k_0$ is a finite field, there
are only finitely many $k_0$-rational points on this Chow variety, which
proves the lemma. \hfill \Box
Step V. Suppose $X$ is an abelian variety defined over $k_0$ and $L$ an ample line bundle on $X$ defined over $k_0$. Suppose for a prime $l \neq \text{char } k_0$, Hyp($k_0, X, l$) holds. Let $W \subset V_l(X)$ be a subspace of $V_l(X)$ which is $G$-stable and is maximal isotropic for the skew-symmetric form $E^L$. Then there is an element $u \in E$ with $u(V_l(X)) = W$.

Proof. Set $T = T_l(X)$, $V = V_l(X)$ and for each integer $n \geq 0$,

$$T_n = (T \cap W) + l^nT$$

If $\psi_n : T_n(X) \rightarrow X_{p^n}$ is the natural homomorphism, set $K_n = \psi_n(T_n)$, $Y_n = X/K_n$ and let $\pi_n : X \rightarrow Y_n$ be the natural homomorphism. Then $(l^n)_X$ factors as $X \xrightarrow{\pi_n} Y_n \xrightarrow{\lambda_n} X$. Since $\pi_n \circ \lambda_n \circ \pi_n = l^n \pi_n$, we obtain that $\pi_n \circ \lambda_n = (l^n)_{Y_n}$, so that

$$\lambda_n((Y_n)^{p^n}) = \ker \pi_n = K_n.$$

Furthermore, for any $m \geq n$, $\lambda_n((Y_n)^{p^m}) \supset (\lambda_n \circ \pi_n)(X_{p^m}) = X_{p^{m-n}}$, so that $T_l(\lambda_n(T_l(Y_n))) \supset l^nT_l(X), T_l(\lambda_n)(T_l(Y_n)) = T_n$.

We now verify that $Y_n$ is an abelian variety defined over $k_0$ and that $\lambda_n$ is a $k_0$-morphism. First note that if $X = X_0 \otimes_{k_0} k$ where $X_0$ is a group scheme over $k_0$, the points of $X_{p^n}$, are separably algebraic over $k_0$. In fact, since $(l^n)_X : X \rightarrow X$ is étale, so is $(l^n)_X : X_0 \rightarrow X_0$, so that $(l^n)^{-1}_X(0)$ consists of points whose residue fields are separably algebraic over $k_0$. Further, since $W$ and hence $(T \cap W) + l^nT$ are $G$-stable by assumption, $K_n$ is also $G$-stable. Thus the fact that $Y_n$ as a variety is defined over $k_0$ and $\pi_n : X \rightarrow Y_n$ is defined over $k_0$ follow from the following general □

Lemma 2. Let $X$ be a quasi-projective variety defined over $k_0$ and $\Pi$ a finite group of automorphisms of $X$ such that

(i) there is a separably algebraic extension of $k_0$ over which the automorphisms of $\Pi$ are defined;

(ii) for any automorphism $\sigma$ of the algebraic closure $\bar{k}_0$ of $k_0$ over $k_0$, $\Pi^\sigma = \Pi$. 

Appendix I - The Theorem of Tate 173
Then $X/\Pi$ is defined over $k_0$ and the natural map $X \to X/\Pi$ is defined over $k_0$.

139 Proof. Choose a Galois extension $k_1/k_0$ over which the automorphisms of $\Pi$ are defined. If $U$ is a $k_0$-affine open subset of $X$, $\bigcap_{\lambda \in \Pi} \lambda U$ is again $k_0$-affine open and $\Pi$-stable, by assumption (ii) of the lemma. Thus, we may assume $X$ affine, $X = \text{Spec } A$, $A = A_0 \otimes_{k_0} k$, $A_0$ being a $k_0$-algebra.

If $A_1 = A_0 \otimes_{k_0} k_1$, $\Pi$ operates on $A_1$, and $A_1^\pi \otimes_{k_1} k = A_1^{\Pi}$. Further, $G = \text{Gal}(k_1/k_0)$ operates on $A_1$, and since by assumption $\lambda \Pi \lambda^{-1} = \Pi$ for any $\lambda \in G$, it follows that $A_1^{\Pi}$ is $G$-stable. Let $B$ be the $k_0$-algebra of $G$-invariants, and $\{\theta_i\}$ a basis of $k_1/k_0$. If $\sum a_i \otimes \theta_i \in A_1^{\Pi}$, $a_i \in A_0$, then $\lambda(\sum a_i \otimes \theta_i) = \sum a_i \otimes \lambda(\theta_i) \in A_1^\pi$, and since $\det(\lambda(\theta_i))_{\lambda \in G,i} \neq 0$, $a_i \otimes 1 \in A_1^{\Pi} \cap A_0 \subset B$, which proves that $A_1^{\Pi} = B \otimes_{k_0} k_1$.

This prove the lemma.

Thus, as a variety, $Y_n$ is defined over $k_0$ and $\pi_n : X \to Y_n$ is defined over $k_0$, so that $\pi_n(0)$ is $k_0$-rational. Since the addition map $m : Y_n \times Y_n \to Y_n$ and the inverse $I : Y_n \to Y_n$ are defined over a separably algebraic extension of $k_0$ and are invariant under the action of $\text{Gal}(k_0/k_0)$, they are again defined over $k_0$. Hence $Y_n$ is defined over $k_0$ as an abelian variety.

Now, $(I^n)_X = \lambda_n \circ \pi_n$ and $\pi_n$ are defined over $k_0$, hence $\lambda_n$ is defined over $k_0$, since for a $k_0$-regular function $\varphi$ on an open subset of $X$, $\varphi \circ \lambda_n$ is $k_1$-regular for a Galois extension $k_1$ of $k_0$ and invariant under $\text{Gal}(k_1/k_0)$ since $\varphi \circ \lambda_n \circ \pi_n = \varphi \circ (I^n)_X$ is.

Let $d$ be the degree of the ample line bundle $L$ on $X$. We shall produce on ample line bundle of degree $2^g \cdot d$ defined over $k_0$ on each $Y_n$. We have

$$e_l(x, \varphi_{\lambda_n(L)}(y)) = E^{l\lambda_n(L)}(x, y) = E^L(\lambda_n(x), \lambda_n(y)) \in e^L(T_n, T_n) = e^L(l^n T, T \cap W + l^n T) \subset l^n M_l$$

for any $x, y \in T_l(Y_n)$, since $W$ is isotropic for $e^L$. Since $e_l : T_l(Y_n) \times T_l(Y_n) \to M_l$ is non-degenerate, it follows that $\varphi_{\lambda_n(L)}(T_l(X)) \subset l^n T_l(X)$, $\varphi_{\lambda_n(L)} = l^n \psi$ for some $\psi : Y_n \to Y_n$. 
It follows from the theorem of §23 that \( \psi = \varphi L_n \) for some line bundle \( L_n \) on \( Y_n \) defined over the algebraic closure, hence over some normal extension of \( k_0 \). We may assume that \( L_n \) is symmetric. Hence, if \( p \) denotes the characteristic of \( k_0 \) if this is positive and \( p = 1 \) if the characteristic is zero, for a suitable integer \( N > 0 \), \( L_n^{p^N} \) is defined over a Galois extension \( k_1 \) of \( k_0 \). We now have

**Lemma 3.** Let \( Y \) be an abelian variety defined over \( k_0 \) and \( L \in \text{Pic}^0 Y \) a line bundle defined over the algebraic closure \( \bar{k}_0 \) of \( k_0 \). Let \( \sigma \in \text{Gal}(\bar{k}_0/k_0) \), and denote by \( \sigma(L) \) the line bundle on \( Y \) defined over \( \bar{k}_0 \) obtained by pulling back \( L \) by the morphism \( 1_{Y_0} \times \text{Spec} \sigma : Y_0 \otimes_{k_0} \bar{k}_0 \to Y_0 \otimes_{k_0} \bar{k}_0 \). Then \( \sigma(L) \in \text{Pic}^0 Y \).

**Proof.** Let \( M \) be an ample line bundle on \( Y \) defined over \( k_0 \), and consider the line bundle \( N = m^*(M) \otimes p_1^*(M)^{-1} \otimes p_2^*(M)^{-1} \) on \( Y \times Y \). We can find an algebraic point \( y \in Y \) such that \( N|\{y\} \times Y = L \). It is then easy to see that \( N|\{\sigma y\} \times Y = \sigma(L) \), so that \( \sigma(L) \in \text{Pic}^0 Y \).

We shall make use of the notation \( \sigma(L) \) introduced in the lemma in future. Further, if \( L_1 \) and \( L_2 \) are two line bundles on \( Y \) with \( L_1 \otimes L_2^{-1} \in \text{Pic}^0 Y \), we shall write \( L_1 \equiv L_2 \).

Resuming the earlier discussion, if \( \sigma \in \text{Gal}(k_1/k_0) \), we see that \( \sigma(L_n^{p^N}) \) is also symmetric, and \( \sigma(L_n^{p^N}) p^{n} = \lambda_n^*(L^{p^N}) \), so that since \( \text{NS}(Y_n) \) is torsion-free \( \sigma(L_n^{p^N}) \equiv L_n^{p^N} \) for every \( \sigma \in \text{Gal}(k_1/k_0) \). Hence, \( \sigma(L_n^{p^N}) \) and \( L_n^{p^N} \) differ by an element of order 2 in \( \text{Pic}^0 Y \). Thus, if we put \( M_n = L_n^{2p^N} \), we have \( \sigma(M_n) \simeq M_n \) for every \( \sigma \in \text{Gal}(k_1/k_0) \) and \( M_n^p = \lambda_n^*(L_n^{2p^N}) \equiv L_n^{2p^Np} \). We now have \( \square \)

**Lemma 4.** Let \( Y \) be a complete variety defined over \( k_0 \) with a \( k_0 \)-rational point, \( k_1 \) a Galois extension of \( k_0 \) and \( L \) a line bundle on \( Y \) defined over \( k_1 \) such that for every \( \sigma \in \text{Gal}(k_1/k_0) \), \( \sigma(L) \simeq L \). Then \( L \) can be defined over \( k_0 \).

**Proof.** Put \( X = X_0 \otimes_{k_0} k \), \( X_1 = X_0 \otimes_{k_0} k_1 \) and let \( \pi : X_1 \to X_0 \) the natural morphism. Since projective modules of constant rank over semi-local rings are free, we can find an affine covering \( \{U_i\}_{i \in I} \) of \( X_0 \) such that
$L/\pi^{-1}(U_i)$ is free. Let $\{\alpha_{ij}\}$ be the 1-cocycle with respect to the covering $\{\pi^{-1}(U_i)\}$ with values in $O_{X_1}^*$ defining $L$. Our assumption implies that for any $\sigma \in G = \text{Gal}(k_1/k_0)$, we have $\beta_{i,\sigma} \in \Gamma(\pi^{-1}(U_i), O_{X_1}^*)$ such that

$$\frac{\sigma(\alpha_{ij})}{\alpha_{ij}} = \beta_{i,\sigma},$$

If $y_0$ is a $k_0$-rational point of $X_0$ with $y_0 \in U_{i_0}$ and $y_1 = \pi^{-1}(y_0)$, by dividing the $\beta_{j,\sigma}$ by $\beta_{i_0,\sigma}(y_1)$, we may assume that $\beta_{i_0,\sigma}(y_1) = 1$. Now,

$$\frac{\sigma\tau(\alpha_{ij})}{\alpha_{ij}} = \frac{\beta_{i,\sigma\tau}}{\beta_{j,\sigma\tau}} = \frac{\sigma(\alpha_{ij})}{\sigma(\alpha_{ij})}, \quad \frac{\beta_{i,\sigma}}{\beta_{j,\sigma}},$$

so that for any $\sigma, \tau \in G, i, j \in I$,

$$\beta_{i,\sigma\tau}\sigma(\beta_{i,\tau})^{-1}\beta_{i,\sigma}^{-1} = \beta_{j,\sigma\tau}\sigma(\beta_{j,\tau})^{-1}\beta_{j,\sigma}^{-1} \text{ in } U_i \cap U_j.$$ 

Since $X$ is complete, $\beta_{i,\sigma\tau}\sigma(\beta_{i,\tau})^{-1}\beta_{i,\sigma}^{-1} = C_{\sigma,\tau}$ for all $i$, and taking $i = i_0$ and evaluating at $y_1$, we see that

$$\sigma(\beta_{i,\tau}) \beta_{i,\sigma\tau}^{-1} \beta_{i,\sigma}^{-1} = 1.$$

Grant for the moment that if $A$ is any local ring of $X_0$ and $B = A \otimes_{k_0} k_1$, and if $B^*$ is the group of units of $B$, $H^1(G, B^*) = (1)$. We deduce that there is a covering $\{U_{i,\alpha}\}_{\alpha \in A_i}$ of $U_i$ and $\gamma_{i,\alpha} \in \Gamma(\pi^{-1}(U_{i,\alpha}), O_{X_1}^*)$ such that

$$\beta_{i,\sigma} = \frac{\sigma(\gamma_{i,\alpha})}{\gamma_{i,\alpha}} \text{ in } \pi^{-1}(U_{i,\alpha}).$$

The cocycle $\frac{\gamma_{j\beta}}{\gamma_{i\alpha}}$ with respect to the covering $\{U_{i,\alpha}\}_{\alpha \in A_i}$ is cohomologous to $\{\alpha_{ij}\}$, and we have

$$\sigma \left( \frac{\gamma_{ji}}{\gamma_{i\alpha}} \right) = \frac{\beta_{i,\sigma}}{\beta_{j,\sigma}} \cdot \alpha_{ij} \frac{\beta_{j,\sigma}}{\beta_{i,\sigma}} \gamma_{j,\beta} \gamma_{i,\alpha}^{-1} = \frac{\gamma_{j,\beta}}{\gamma_{i,\alpha}} \alpha_{ij},$$

$$\alpha_{ij} \frac{\gamma_{j,\beta}}{\gamma_{i,\alpha}} \in \Gamma(U_{i,\alpha} \cap U_{j,\beta}, O_{X_0}^*).$$
It only remains to show that if $A$ is the local ring of a point on $X_0$ and $B = k_1 \otimes_{k_0} A$, $H^1(G, B^*) = \{1\}$. Let $R$ be the quotient field of $B$; we then have the exact sequence

$$H^0(G, R^*) \to H^0(G, R^*/B^*) \to H^1(G, B) \to H^1(G, R^*) = \{1\}.$$ 

An element of $H^0(G, R^*/B^*)$ is represented by an element $f \in R^*$ such that $\frac{\sigma f}{f} \in B^*$ for all $\sigma \in G$, and we shall show that we can write $f = gu$ where $g \in H^0(G, R^*)$ and $u \in B^*$. Writing $f = \frac{f_0}{F}$ with $f_0 \in B$, $F \in A$, we see that we may assume that $f \in B$. Now, since $\frac{\sigma f}{f} \in B^*$ for all $\sigma \in G$, the ideal $Bf$ is $G$-invariant, hence of the form $B\mathfrak{u}$, $\mathfrak{u}$ being an ideal in $A$. But now, since $Bf \simeq k_1 \otimes_{k_0} \mathfrak{u}$, it is principal, hence an ideal in $A$. Thus, $Bf = Bg$ for some $g \in A$ and $f = gu$, $g \in A$, $u \in B^*$. □

This completes the proof of Lemma 4.

It follows that the line bundle $M_n$ on $Y_n$ is defined over $k_0$. Now, the g.c.d. of $2p^N$ and $l^n$ is 1 or 2 according as $l$ is 2 or not. Hence, we can find integers $a, b$ such that $2ap^N + bl^n = 2$. Define $N_n = M_n^a \otimes \lambda_n^* (L)^b$, so that $N_n$ is defined over $k_0$. Further,

$$N_n \equiv L_n^{2ap^N + bl^n} = L_n^2,$$

so that $N_n$ is ample with $\chi(N_n) = 2^g \chi(L_n) = 2^g \cdot l^{-ng} \chi(\lambda_n^*(L)) = 2^g \cdot l^{-ng} \deg \lambda_n \chi(L) = 2^g \chi(L) = 2^g d$.

An alternative way of producing an ample line bundle of degree $2^g d$ on $Y_n$ is to observe that (i) if $Y$ is an abelian variety defined over $k_0$, and we construct $\hat{Y}$ as $Y/K(L)$ for a line bundle $L$ defined over $k_0$, $\hat{Y}$ is defined over $k_0$ and the Poincaré bundle $P$ on $Y \times \hat{Y}$ is defined over $k_0$; (ii) if $\varphi_{\lambda_n^*(L)} = l^n \psi$, since $\lambda_n^*(L)$ is defined over $k_0$, so is $\varphi_{\lambda_n(L)}$ and hence also $\psi$; and finally; (iii) if $P_n$ is the Poincaré bundle on $Y_n \times \hat{Y}_n$ and $\chi = (1, \psi) : Y_n \to Y_n \times \hat{Y}_n$, then $\chi^*(P_n) = N_n$ is a line bundle defined over $k_0$ with $\varphi = 2\psi$ (see §13), so that $\chi(N_n)^2 = \deg \varphi_{N_n} = 2^g \deg \psi = 2^g l^{-2ng} \deg \lambda_n^*(L) = 2^g l^{-2ng} \times (\deg \lambda_n)^2 \chi(L)^2 = 2^g \chi(L)^2$. 

\[\text{Appendix I - The Theorem of Tate} 177\]
Anyhow, we deduce from Hyp($k_0, X, l$) that there is an infinite set $I$ of natural integers with smallest integer $n$ and isomorphisms $v_i : Y_n \sim Y_i$ for all $i \in I$. Consider the elements $u_i = \lambda_i v_i \lambda_n^{-1} \in \text{End}^0 X$ and their images $u'_i \in \text{End}_Q(V_i)$. We have $u'_i(T_n) = T_i \subset T_n$ for $i \in I$, and since $\text{End}_Z(T_n)$ is compact, we can select a subsequence $(u'_j)_{j \in J}$ which converges to a limit $u'$. Since $E$ is closed in $\text{End}(V_i)$ and $u'_j \in E$, $u'$ also belongs to $E$. Since $T_n$ is compact, $u'(T_n)$ consists of elements of the form $x = \lim x_j$ where $x_j \in u_j(T_n) = T_j$, and since the sets $T_j$ are decreasing, it follows that

$$u(T_n) = \bigcap_{j \in J} u_j(T_n) = \bigcap_{j \in J} T_j = T \cap W.$$ 

Hence $u(V) = W$.

This completes the proof of Step V.

**Step VI.** Suppose that for any finite algebraic extension $k_1$ of $k_0$, Hyp($k_1, X, l$) holds, and that $F$ is isomorphic as a $Q_l$-algebra to a direct product of copies of $Q_l$. Then (4) is an isomorphism.

**Proof.** Replacing $k_0$ by a finite algebraic extension $k_1$ over which all elements of $\text{End} X$ are defined and which is such that $\text{Gal}(\bar{k}_1/k_1)$ generates $F$ in $\text{End}(V_i)$, we may assume that $k_0$ itself has these properties. Let $D$ be the commutant of $E$ in $\text{End}(V_i)$, so that $D \supset F$. We first show that any isotropic subspace $W$ for $E^L$ which is $F$-stable is also $D$-stable. We proceed by downward induction on dim $W$. If $W$ is maximal isotropic, i.e. if dim $W = g$, we can by Step V find a $u \in E$ such that $u(V) = W$, and hence $DW = DuV = uDV = uV = W$, which proves the assertion. Suppose then that dim $W = r < g$ and the assertion holds for $F$-stable isotropic subspaces of dimension $r+1$. The orthogonal complement $W^\perp$ of $W$ for $E^L$ is also $F$-stable, since $E^L$ is invariant under the action of $\text{Gal}(\bar{k}_0/k_0)$. Further, since any simple $F$-module is one-dimensional and dim $W^\perp - \text{dim} W = 2g - 2 \text{dim} W = 2(g - r) \geq 2(g - g + 1) = 2$, we can find $F$-stable one-dimensional subspaces $L_1$ and $L_2$ of $W^\perp$ such that the sum $W + L_1 + L_2$ is direct. By induction hypothesis, $W + L_1$ and $W + L_2$ are $D$-stable, hence so is their intersection $W$. This completes
the induction. We deduce that any eigen-vector for \( F \) in \( V \) is also an eigen-vector for \( D \). It follows that \( D \subset F \). (The decomposition of \( V \) into factors \( V_i \) corresponding to the simple factors of \( F \) reduces this assertion to the evident statement that an endomorphism of \( V_i \) for which every element of \( V_i \) is an eigen-vector is a scalar multiplication). Hence \( F = D \), completing the proof of Step VI. \( \square \)

**Step VII. End of proof of theorem.**

We assume from now on that \( k_0 \) is a finite field. By replacing it by a finite extension if necessary, we may assume that every element of \( \text{End} X \) is defined over \( k_0 \). Let \( \pi \) be the Frobenius morphism over \( k_0 \). Then \( \pi \) belongs to the center of \( \text{End}^0 X \), and hence \( \mathbb{Q}[\pi] \) is a commutative semi-simple subalgebra of \( \text{End}^0 X \). We shall first show that there are an infinity of primes \( l \) for which \( \mathbb{Q}_l \otimes \mathbb{Q}_l \mathbb{Q}[\pi] \) is isomorphic as a \( \mathbb{Q}_l \)-algebra to a direct product of copies of \( \mathbb{Q}_l \).

In fact, writing \( \mathbb{Q}[\pi] = K_1 \times \ldots \times K_r \) where \( K_i \) are finite extensions of \( \mathbb{Q} \), it suffices to show that for an infinity of primes \( l \), each \( \mathbb{Q}_l \otimes K_i \) is isomorphic to a product of copies of \( \mathbb{Q}_l \). Let \( K \) be a finite Galois extension of \( \mathbb{Q} \) in which all the \( K_i \) are embeddable. Then it suffices to show that for an infinity of \( l \), \( K \otimes \mathbb{Q}_l \mathbb{Q}_l \mathbb{Q}\) splits as a product of copies of \( \mathbb{Q}_l \). It suffices for this that there is one simple factor of \( K \otimes \mathbb{Q}_l \mathbb{Q}_l \) isomorphic to \( \mathbb{Q}_l \). In fact, if \( K \otimes \mathbb{Q}_l \mathbb{Q}_l \approx L_1 \times \ldots \times L_k \), the Galois group \( \pi \) of \( K/\mathbb{Q} \) permutes the factors \( L_i \). It also acts transitively on the simple factors. For, if not, suppose \( L_1 \times \ldots \times L_r \) is \( \pi \)-stable; then the element \((1, 1, \ldots, 1, 0, 0, 0) \in L_1 \times \ldots \times L_k \) is \( \pi \)-stable. On the other hand, since \( \pi \) fixes only the elements of \( \mathbb{Q} \) in \( K \), it fixes only the elements of \( \mathbb{Q}_l \) in \( \mathbb{Q}_l \otimes \mathbb{Q}_l K \), that is, elements of the form \((\alpha, \alpha, \ldots, \alpha) \in L_1 \times \ldots \times L_k \) with \( \alpha \in \mathbb{Q}_l \). This proves the assertion.

Now, choose an algebraic integer \( \alpha \) of \( K \) generating \( K \) over \( \mathbb{Q} \), and let \( F(X) \in \mathbb{Z}[X] \) be its irreducible monic polynomial over \( \mathbb{Q} \). Since \( K \otimes \mathbb{Q}_l \mathbb{Q}_l \approx \mathbb{Q}_l[X]/(F(X)) \), it is enough to find an infinity of \( l \) for which \( F(X) \) has a zero in \( \mathbb{Q}_l \). Let \( \Delta \) be the discriminant of \( F(X) \), and \( l \) any prime not dividing \( \Delta \) such that \( F(X) \equiv 0 \pmod{l} \) has a solution \( n \) in \( \mathbb{Z} \). Then \( F'(n) \not\equiv 0 \pmod{l} \), so that by Hensel’s lemma, \( n \) can be refined to a
root of $F$ in $\mathbb{Z}_l$. Thus, we are reduced to proving the following

**Lemma 5.** Let $F(X) \in \mathbb{Z}[X]$ be a non-constant polynomial. Then there are an infinity of primes $l$ for which $F(X) \equiv 0 \pmod{l}$ has a solution in $\mathbb{Z}$.

**Proof.** Let $F(X) = a_0X^n + a_1X^{n-1} + \ldots + a_n$. The lemma being trivial when $a_n = 0$, since $X$ is a factor of $F(X)$ in this case, we may assume $a_n \neq 0$. Further, by substituting $a_nX$ for $X$ in $F$ and removing the common factor $a_n$, we may assume $a_n = 1$. Let $S$ be a finite set of primes $p$. If $N = \prod_{p \in S} p$, then

$$F(vN) = a_0v^nN^n + \ldots + a_{n-1}vN + 1 \equiv 1 \pmod{N}$$

so that no prime of $S$ divides $F(vN)$. On the other hand, $F(vN) \neq \pm 1$ for $v$ large, hence has a prime factor $l$ not belonging to $S$.

Next, we show that for all $l \neq \text{char.} k_0$, the dimension of $\text{End}_{\mathbb{Q}_l} V^{(G)}_l$ is the same. Again, assume that every element of $\text{End} X$ is defined over $k_0$, so that the Frobenius $\pi$ belongs to the center of $\text{End}^0 X$, hence to the centre of $\mathbb{Q}_l \otimes \mathbb{Q} \text{End}^0 X$. Then $\mathbb{Q}_l[\pi]$ is semi-simple and $V_l$ is a $\mathbb{Q}_l[\pi]$-module, so that the image $\pi'$ of $\pi$ in $\text{End}_{\mathbb{Q}_l} V_l$ is semi-simple. The characteristic polynomial $P(t)$ of $\pi'$ in $\text{End}_{\mathbb{Q}_l} V_l$ has coefficients in $\mathbb{Z}$ independent of $l$. Further, the closed subgroups of $\text{Gal}(\overline{k}_0/k_0)$ generated by $\pi^n!$ form a fundamental system of neighborhoods of $e$ in this group, so that $\text{End}_{\mathbb{Q}_l} V^{(G)}_l$ is the commutant of $\pi^n!$ in $\text{End}_{\mathbb{Q}_l} V_l$ for $n$ large. The characteristic polynomial of $\pi^n!$ has for roots $\theta_{1}^{n!}, \ldots, \theta_{2g}^{n!}$ where $\theta_1, \ldots, \theta_{2g}$ are the roots of $P(t)$ repeated with multiplicity. For all $n$ large, the number of distinct elements of $\theta_1^{n!}, \ldots, \theta_{2g}^{n!}$ as well as their multiplicities is the same. Thus, our assertion is a consequence of the following lemma, applied to an algebraic closure of $\mathbb{Q}_l$. □

**Lemma 6.** Let $A$ and $B$ be absolutely semi-simple endomorphisms of two vector spaces $V$ and $W$ of finite dimensions over a field $k$ respectively, with characteristic polynomials $P_A$ and $P_B$. Let

$$P_A = \prod_{p} p^{m(p)},$$
Appendix I - The Theorem of Tate

$$P_B = \prod_p p^{n(p)}$$

be the decompositions of $P_A$ and $P_B$ as products of powers of distinct irreducible monic polynomials $p$. Then the vector space

$$E = \{ \varphi \in \text{Hom}_k(V, W) | \varphi A = B \varphi \}$$

has dimension

$$r(P_A, P_B) = \sum_p m(p)n(p) \deg p,$$

and this integer is invariant under any extension of the base field $k$.

**Proof.** Make $V$ (resp. $W$) into a $k[X]$-module by making $X$ act through $A$ (resp. $B$). Denote the $k[X]$-module $k[X]/(p(X))$ by $M_p$. Because of our assumption of semi-simplicity, we have isomorphisms of $k[X]$-modules

$$V \cong \prod_p M_p^{m(p)},$$

$$W \cong \prod_p M_p^{n(p)}.$$ 

Now, the $M_p$ are non-isomorphic simple $k[X]$-modules for distinct $p$, and $E$ is nothing but $\text{Hom}_{k[X]}(V, W)$. Since $\dim_k \text{Hom}_{k[X]}(M_p, M_p) = \dim_k M_p = \deg p$, and since $E$ clearly ‘commutes with base extension’, the lemma follows.

The main Theorem is a consequence of what we have proved, combined with Steps III and VI. □

**Remark.** The theorem can be stated in the following seemingly stronger form:

**Theorem 1’.** Let $X$ and $Y$ be abelian varieties defined over a finite field $k_0$, and let $\text{Hom}_{k_0}(X, Y)$ be the group of homomorphisms of $X$ into $Y$ defined over $k_0$. If $G$ is the Galois group of the algebraic closure of $k_0$ over $k_0$, we have an isomorphism

$$\mathbb{Z}_l \otimes \mathbb{Z} \text{Hom}_{k_0}(X, Y) \sim \text{Hom}_{\mathbb{Z}_l}(T_l(X), T_l(Y))^G.$$
Proof. Take $G$-invariants on both sides of the isomorphism (2). \qed

Applications. We give some easy consequences of Theorem 1. We shall make our statements over a fixed finite field. The ‘geometric’ statements over the algebraic closure are easily obtained from these. We shall consistently use the notation $r(f, g)$ for two polynomials $f$ and $g$, introduced in Lemma 6. Further, as we have shown above that if $X$ is an abelian variety defined over a finite field $k_0$ with Frobenius morphism $\pi$, then the Frobenius morphism $\pi^n$ over a finite extension of $k_0$ induces semi-simple endomorphisms of $V_l(X)$ over $\mathbb{Q}_l$, it follows since $\mathbb{Q}_l$ is of characteristic zero that $\pi$ itself induces (absolutely) semi-simple endomorphisms of $V_l(X)$ for all $l \neq \text{char.} k_0$. Thus, the structure of $V_l(X)$ as a module over the Galois group of $\overline{k}_0$ over $k_0$ is uniquely determined by the characteristic polynomial of $\pi$, as explained in the proof of Lemma 6.

We now have

Theorem 2. Let $X$ and $Y$ be abelian varieties defined over a finite field $k_0$, and let $P_X$ and $P_Y$ be the characteristic polynomials of their Frobenius endomorphisms relative to $k_0$. Then

(a) we have
$$\text{rank}(\text{Hom}_{k_0}(X, Y)) = r(P_X, P_Y);$$

(b) the following statements are equivalent:

(b$_1$) $Y$ is $k_0$-isogenous to an abelian subvariety of $X$ defined over $k_0$,
(b$_2$) $V_l(Y)$ is $G$-isomorphic to a $G$-subspace of $V_l(X)$ for some $l$,
(b$_3$) $P_Y$ divides $P_X$;

(c) the following statements are equivalent:

(c$_1$) $X$ and $Y$ are $k_0$-isogenous,
(c$_2$) $P_X = P_Y$,
(c$_3$) $X$ and $Y$ have the same number of $k_1$-rational points for every finite extension $k_1$ of $k_0$. 

Appendix I - The Theorem of Tate

Proof. (a) follows from Theorem 1 and Lemma 6 since the Frobenius morphism generates the Galois group in the topological sense. The implications \((b_1) \Rightarrow (b_2) \Leftrightarrow (b_3)\) are clear, in view of our earlier remarks. We show that \((b_2) \Rightarrow (b_1)\). If \((b_2)\) holds, we can find an injective \(G\)-homomorphism \(\varphi\) of \(T_1(Y)\) into \(T_1(X)\). Then \(\varphi\) is in the image of \(Z_1 \otimes_Z \text{Hom}_{k_0}(X, Y)\), so that we can find \(\psi \in \text{Hom}_{k_0}(X, Y)\) such that \(T_1(\psi)\) approximates arbitrarily closely to \(\varphi\), in particular with \(T_1(\psi)\) injective.

If \(\psi\) is not an isogeny, we can find an abelian subvariety \(Z\) of \(Y\) in the kernel of \(\psi\), and the submodule \(T_1(Z)\) of \(T_1(Y)\) would be in the kernel of \(T_1(\psi)\). Hence \(\psi\) is an isogeny, proving (b).

The equivalence \((c_1) \Leftrightarrow (c_2)\) is a special case of \((b_1) \Leftrightarrow (b_3)\) when \(\dim X = \dim Y\). Further, we have seen during the proof of the Riemann hypothesis in §20 that if \(\omega_i (i \in I)\) and \(\omega'_j (j \in J)\) are the roots of \(P_X\) and \(P_Y\) respectively and \(N_n\) and \(N'_n\) are the number of rational points of \(X\) and \(Y\) respectively in the extension of degree \(n\) of \(k_0\), we have

\[
N_n = \prod_i (1 - \omega^n_i),
\]

\[
N'_n = \prod_j (1 - \omega'^n_j);
\]

thus, we have to show that \(P_X = P_Y \Leftrightarrow \prod_i (1 - \omega^n_i) = \prod_j (1 - \omega'^n_j)\) for every \(n \geq 0\). The implication \(\Rightarrow\) is obvious. To prove the other implication, note that

\[
\prod_{i \in I} (1 - \omega^n_i) = \sum_{S \subset I} (-1)^{|S|} \omega_S^n,
\]

\[
\prod_{j \in J} (1 - \omega'^n_j) = \prod_{T \subset J} (-1)^{|T|} \omega_T'^n
\]

where \(|S|, |T|\) denote the respective cardinalities and \(\omega_S = \prod_{i \in S} \omega_i, \omega_T' = \prod_{j \in T} \omega'_j\). Multiplying the given equation by \(t^n\), where \(t\) is a variable, and summing as formal power series, we obtain

\[
\sum_{S \subset I} (-1)^{|S|} \frac{1}{1 - t\omega_S} = \sum_{T \subset J} (-1)^{|T|} \frac{1}{1 - t\omega_T}
\]
Since $|\omega_i| = |\omega'_j| = q^{1/2}$, comparing the poles on both sides on the circle $|t| = q^{1/2}$, we obtain that there is a bijection $\sigma : I \to J$ such that $\omega_i = \omega'_{\sigma(j)}$. Hence, $P_X = P_Y$.

Before we come to the next theorem, we need some preliminaries. Let $X$ be an abelian variety defined over $k_0$, so that $X = X_0 \otimes_{k_0} k$ for some group-scheme $X_0$ over $k_0$. Let $Y$ be an abelian subvariety of $X$, which is a $k_0$-closed subset, so that if $\lambda : X \to X_0$ is the natural morphism, there is a closed subset $Y_0$ of $X_0$ with $\lambda^{-1}(Y_0) = Y$ in the set-theoretic sense. We give $Y_0$ the structure of a reduced subscheme of $X_0$. If $m_0 : X_0 \times_{k_0} X_0 \to X_0$ is the multiplication morphism, our hypothesis implies the set-theoretic inclusion $m_0(Y_0 \times_{k_0} Y_0) \subset Y$. Hence $m_0$ restricts to a morphism $m_0 : (Y_0 \times_{k_0} Y_0)_{\text{red.}} \to Y_0$. If we can assert that $Y = Y_0 \otimes_{k_0} k$ and $Y_0 \times_{k_0} Y_0$ are reduced, it would follow that $Y$ is an abelian variety defined over $k_0$. Both of these are consequences of the assertion that the function field $R_{k_0}(Y_0)$ is a regular extension of $k_0$, or equivalently that $R_{k_0}(Y_0)$ is a separable extension of $k_0$. This is always true (vide S. Lang, *Abelian varieties*, Chap. I), but we shall not prove this, since we shall need it only when $k_0$ is a finite (hence perfect) field, so that this is trivially satisfied.

Next, suppose $X$ is an abelian variety defined over $k_0$, and $Y$ an abelian subvariety which is $k_0$-closed. We want to show that there is an abelian subvariety $Z$ of $X$ defined over $k_0$ such that $Y + Z = X$ and $Y \cap Z$ is finite. We know (vide §18, proof of Theorem 1) that if $L$ is an ample line bundle on $X$, we can take $Z$ to be the connected component of 0 of the group $Z' = \{ z \in X | T^*_Z(L) \otimes L^{-1}|_Y \text{ is trivial} \}$, so that if we can ensure that $Z$ is defined over $k_0$ for a suitable choice of $L$, we are through. Now if we choose $L$ to be a line bundle defined over $k_0$, $Z'$ is defined over the algebraic closure $\bar{k}_0$ of $k_0$ and is stable for all automorphisms of $\bar{k}_0$ over $k_0$. Hence $Z'$ is $k_0$-closed. Further, the conjugations of $\bar{k}_0$ over $k_0$ permute the components of $Z'$, and since $Z$ is a component of $Z'$ containing the $k_0$-rational point 0, $Z$ is also stable under these conjugations. Hence $Z$ is $k_0$-closed, and it follows from the comments of the earlier paragraph that $Z$ is an abelian variety defined over $k_0$.

If follows from this by repeating the arguments of §18 that if we call
an abelian variety $X$ defined over $k_0$ to be $k_0$-simple if it does not contain an abelian subvariety $Y$ defined over $k_0$ with $Y \neq \{0\}, Y \neq X$, then (i) any abelian variety defined over $k_0$ is $k_0$-isogenous to a product of $k_0$-simple abelian varieties, and (ii) if $X$ is $k_0$-isogenous to a product $X_1^{n_1} \times \ldots \times X_r^{n_r}$, where $X_i$ are $k_0$-simple and $X_i$ and $X_j$ are not $k_0$-isogenous if $i \neq j$, then $\text{End}_{k_0}^0 X \cong M_{n_1}(D_1) \times \ldots \times M_{n_r}(D_k)$ where $D_i = \text{End}_{k_0}^0 (X_i)$ are division algebras of finite rank over $Q$. \hfill \square

We now have

**Theorem 3.** Let $X$ be an abelian variety of dimension $g$ defined over a finite field $k_0$. Let $\pi$ be the Frobenius endomorphism of $X$ relative to $k_0$ and $P$ its characteristic polynomial. We then have the following statements:

(a) The algebra $F = Q[\pi]$ is the center of the semi-simple algebra $E = \text{End}_{k_0}^0 (X)$;

(b) $\text{End}_{k_0}^0 (X)$ contains a semi-simple $Q$-subalgebra $A$ of rank $2g$ which is maximal commutative;

(c) the following statements are equivalent:

\begin{itemize}
  \item[(c_1)] $[E : Q] = 2g$,
  \item[(c_2)] $P$ has no multiple root,
  \item[(c_3)] $E = F$,
  \item[(c_4)] $E$ is commutative;
\end{itemize}

(d) the following statements are equivalent:

\begin{itemize}
  \item[(d_1)] $[E : Q] = (2g)^2$,
  \item[(d_2)] $P$ is a power of a linear polynomial,
  \item[(d_3)] $F = Q$,
  \item[(d_4)] $E$ is isomorphic to the algebra of $g$ by $g$ matrices over the quaternion division algebra $D_P$ over $Q(P = \text{char } k_0)$ which splits at all primes $l \neq p, \infty$,\hfill \square
(d5) $X$ is $k_0$-isogenous to the $g$-th power of a super-singular curve, all of whose endomorphisms are defined over $k_0$;

(e) $X$ is $k_0$-isogenous to a power of a $k_0$-simple abelian variety if and only if $P$ is a power of a $\mathbb{Q}$-irreducible polynomial. When this is the case, $E$ is a central simple algebra over $F$ which splits at all finite primes $v$ of $F$ not dividing $p$, but does not split at any real prime of $F$.

Proof. If follows from the main theorem that $F_1 = \mathbb{Q}_l \otimes_{\mathbb{Q}} F$ is the center of $E_1 = \mathbb{Q}_l \otimes_{\mathbb{Q}} E$, which proves that $F$ is the center of $E$.

Suppose $E = A_1 \times \ldots \times A_r$ is the expression of $E$ as a product of simple algebras $A_i$ with centers $K_i$. Let $[K_i : \mathbb{Q}] = a_i$, and $[A_i : K_i] = b_i^2$. We can choose subrings $L_i$ of $A_i$ containing $K_i$ with $L_i$ semi-simple and maximal commutative, $[L_i : K_i] = b$. Then $L = L_1 \times \ldots \times L_r$ is a semi-simple $\mathbb{Q}$-subalgebra of $E$ which is maximal commutative, and $[L : \mathbb{Q}] = \sum_1^r a_i b_i$. Now, for any $l$, we have

$$E \otimes_{\mathbb{Q}} \mathbb{Q}_l = \prod_1^r (A_i \otimes_{\mathbb{Q}} \mathbb{Q}_l) = \prod_1^r (A_i \otimes_{K_i} (K_i \otimes_{\mathbb{Q}} \mathbb{Q}_l)) = \prod_1^r \prod_{i=1}^{n_i} A_i \otimes_{K_i} K'_{ij},$$

where $K_i \otimes_{\mathbb{Q}} \mathbb{Q}_l = \prod_{j=1}^{n_i} K'_{ij}$ with $K'_{ij}$ fields. On the other hand, if $P = \prod P_i^{m_i}$ is the decomposition of $P$ over $\mathbb{Q}_l$ into a product of powers of irreducible polynomials over $\mathbb{Q}_l$, and if we consider $T_l(X)$ as a $\mathbb{Q}_l[T]$-module by making $T$ act via $\pi$, we have an isomorphism of $\mathbb{Q}_l[T]$-modules

$$T_l(X) \cong \prod_{v=1}^s \left( \frac{\mathbb{Q}_l[T]}{(P_v)} \right)^{m_v} = \prod_{v=1}^s S_v^{m_v}, S_v = \frac{\mathbb{Q}_l[T]}{(P_v)},$$

so that $E \otimes_{\mathbb{Q}} \mathbb{Q}_l$, being the commutant of $\pi$ in $\text{End} T_l(X)$, is isomorphic to

$$\prod_{v=1}^s M_{m_v}(S_v).$$
Comparing the two factorisations of \( E \otimes Q \mathbb{Q} \) and keeping in mind that \( K'_{ij} \) is the center of \( A_i \otimes K_i K'_{ij} \), we deduce that (i) for any prime \( l \neq p \) and any prime \( v \) of \( K_i \) lying over \( l \), \( A_i \) splits at \( v \) and (ii) there is a partition of \([1, s]\) into \( r \) disjoint subsets \( I_1, \ldots, I_r \) such that

\[
A_i \otimes Q \mathbb{Q} \cong \prod_{j=1}^{n_i} A_i \otimes K_i K'_{ij} \cong \prod_{v \in I_i} M_{m_v}(S_v).
\]

It follows that \( m_v = b_i \) for \( v \in I_i \) and

\[
\sum_{v \in I_i} [S_v : \mathbb{Q}_l] = \sum_{j=1}^{n_i} [K'_{ij} : \mathbb{Q}_l] = [K_i : \mathbb{Q}] = a_i,
\]

so that

\[
\sum_{i=1}^{r} a_i b_i = \sum_{i=1}^{r} \sum_{v \in I_i} m_v [S_v : \mathbb{Q}_l] = \sum_{v=1}^{s} m_v [S_v : \mathbb{Q}_l] = \sum_{v=1}^{s} m_v \deg P_v = \deg P = 2g.
\]

This proves (b).

Since \( F \) is the center of \( E \) and \( E \) contains a maximal commutative subring of rank \( 2g \), (c₁), (c₃) and (c₄) are equivalent, and since \( E \) commutative \( \iff \) \( E_i \) commutative \( \iff \) \( m_v = 1 \) with the above notations, these are also equivalent to (c₂). This proves (c).

Now, \([E : Q] = (2g)^2\) if and only if \( Q_l \otimes Q E \cong M_{2g}(Q_l)\), hence if and only if \( s = 1\), \( S_v = Q_l\) or equivalently, \( P \) is a power of a linear polynomial. In this case, \( Q_l \) is the center of \( Q_l \otimes Q E \), so that \( Q \) is the center of \( E \), and conversely, if this holds, \( Q_l \otimes Q E \) is the commutant of \( Q_l \) in \( \text{End} V_l \), so that it is the whole of \( \text{End} V_l \). Thus (d₁), (d₂) and (d₃) are equivalent. If \( Q_l \otimes Q E = M_{2g}(Q_l)\), \( E \) is a central simple algebra over \( Q \) whose invariants at all finite primes \( l \neq p \) are 0. Since its invariant at the infinite prime is 0 or \( \frac{1}{2} \) and the sum of invariants at all primes is 0, \( E \) is either \( M_{2g}(Q) \) or \( M_g(D_p) \) where \( D_p \) is the quaternion algebra over \( Q \) splitting at all finite primes \( l \neq p \). The first possibility is ruled out, since \( X \) cannot be a product of \( 2g \) abelian varieties. This proves that (d₁) \( \iff \) (d₄). In view of our remarks preceding the theorem, (d₄) is equivalent to saying that \( X \cong C^g \), where \( C \) is an elliptic curve with
End_{k_0} C \simeq D_p. We have then shown that C is supersingular (§22). This proves (d).

Let Q be the product of the distinct irreducible factors of P. Since $F = \mathbb{Q}[\pi]$ is semi-simple, and $P(\pi) = 0$, we have $Q(\pi) = 0$. Further, $\pi$ acts as an endomorphism of $V_l$, any irreducible factor over $\mathbb{Q}_l$ of the characteristic polynomial $P$ divides the minimal polynomial of $\pi$, so that $Q$ is the minimal polynomial of $\pi$ over $\mathbb{Q}$. Now, $X$ is $k_0$-isogenous to a power of a $k_0$-simple abelian variety if and only if $E$ is simple, hence if and only if the center $F = \mathbb{Q}[\pi]$ of $E$ is a field. Since $F \simeq \mathbb{Q}[\pi]/(Q(X))$, $F$ is a field if and only if $Q$ is irreducible, or equivalently, $P$ is the power of an irreducible polynomial $Q$. If $F$ is the center of $E$, we have shown earlier that $E$ splits at any finite prime $v$ of $F$ not dividing $l$. Suppose $v$ is a real imbedding of $F$, so that $\nu(\pi)$ is a real number. Since $\nu(\pi)$ satisfies $P(\nu(\pi)) = 0$ and the roots of $P$ have absolute value $\sqrt{q}$, we must have $\nu(\pi) = \pm \sqrt{q}$. If $q$ is a square, $\nu(\pi) \in \mathbb{Q}$ and $F = \mathbb{Q}$, so that the equivalent condition of (d_3) and (d_4) implies that $E$ does not split at $\infty$. If $q$ is not a square, $F = \mathbb{Q}(\sqrt{p})$. Let $k_1$ be the quadratic extension of $k_0$ and $\pi' = \pi^2$ the Frobenius over $k_1$. Then $\pi'^2 \in \mathbb{Q}$, so that the center $F'$ of $E' = \text{End}_{k_1} X$ is $\mathbb{Q}$. Appealing to (d), we conclude that $E' = M_g(D_p)$.

On the other hand, we have $F' \subset F \subset E \subset E'$, and $E$ is the commutant of $F$ in $E'$. By a known result on central simple algebras, we see that $E$ and $F \otimes F'$ $E'$ define the same element of the Brauer group over $F$, that is, $E$ is the image of $E'$ under the natural map $Br(F') \to Br(F)$. Since both the real primes of $\mathbb{Q}(\sqrt{p})$ lie over the real prime $\infty$ of $\mathbb{Q}$ and $E'$ has invariant $\frac{1}{2}$ at $\infty$ with respect to $F' = \mathbb{Q}$, $E$ has invariant $\frac{1}{2}$ at either of the real primes of $F = \mathbb{Q}(\sqrt{p})$. This completes the proof of (e).

\[\square\]

**Corollary.** Any two elliptic curves defined over finite fields with isomorphic algebras of complex multiplications are isogenous (over the algebraically closed field $k$).

In particular, any two supersingular elliptic curves are isogenous.

**Proof.** Suppose $X$, $Y$ are supersingular elliptic curves. We can choose a common finite field of definition $k_0$ such that $\text{End}_{k_0} X$ and $\text{End}_{k_0} Y$ are quaternion algebras over $\mathbb{Q}$, so that they have $\mathbb{Q}$ for center. Thus,
their Frobenius morphisms $\pi_X$ and $\pi_Y$ lie in $\mathbb{Q}$. Since they must both have absolute value $\sqrt{q}$ where $q = \text{card}(k_0)$, we see that $\pi_X^2 = \pi_Y^2 = q$. Thus, if $k_1$ is the quadratic extension of $k_0$, there is an isomorphism $T_l(X) \sim T_l(Y)$ carrying the action of $\pi'_X$ into $\pi'_Y$, where $\pi'_X = \pi_X^2$ and $\pi'_Y = \pi_Y^2$ are the Frobenius morphisms over $k_1$. By Theorem 2, $X$ and $Y$ are isogenous over $k_1$.

Next suppose $\text{End}^0 X \cong K, \text{End}^0 Y \cong K$ for some imaginary quadratic extension $K$ of $\mathbb{Q}$. Choose a common finite field of definition of $X$ and $Y$ over which all their endomorphisms are defined and all the points of order $p$ are rational. Now, $\mathbb{Q}_p \otimes_{\mathbb{Q}} \text{End}^0 X$ admits a one-dimensional representation in $T_p(X)$. Hence, $p$ splits into a product of two distinct primes $p$ and $p'$ in $K$ which are conjugate, and $\mathbb{Q}_p \otimes_{\mathbb{Q}} \text{End}^0 X \cong K_p \times K_{p'}$. Suppose for instance that $\mathbb{Q}_p \otimes_{\mathbb{Q}} \text{End}^0 X$ acts on $T_p(X)$ via $K_p$. By what we have said, it follows that $\pi_X \equiv 1(p)$, and since $N\text{m}\pi_X$ is a power of $p$, $(\pi_X)$ has to be a power of $p'$ in the ring of integers of $K$. A similar assertion (possibly with $p$ replacing $p'$) holds for $\pi_Y$. By altering the isomorphism $\text{End}^0 Y \cong K$ by the conjugation of $K$ if necessary, we may assume that $(\pi_Y)$ is also a power of $p'$. Since $N\text{m}\pi_X = N\text{m}\pi_Y = q = p^f$, we see that in the ring of integers of $K$, $(\pi_X) = (\pi_Y) = p'^f$ so that $\pi_X$ and $\pi_Y$ differ by a unit, i.e., a root of unity since $K$ is imaginary quadratic. Thus $\pi_X^n = \pi_Y^n$ in $K$ for suitable $n$, and they have the same minimal equation over $\mathbb{Q}$, of degree 2. Since this has to be their characteristic polynomial, $X$ and $Y$ are isogenous over an extension of degree $n$ of $k_0$. \qed
The Geometry of the Monodromy Theorem*

By Lê Dũng Tráng

Introduction. Let \((X, x)\) be the germ of an analytic space and \(f : (X, x) \to (\mathbb{C}, 0)\) be the germ of an analytic function. We shall still denote \(X\) and \(f\) representants of the corresponding germs. Let us suppose \(X \subset U \subset \mathbb{C}^N\) where \(U\) is an open subset of \(\mathbb{C}^N\) and \(X\) is closed in \(U\).

Let us suppose that for any \(t \neq 0\) sufficiently small, \(f = t\) is smooth. It has been proved in [3] or [6] that if \(\epsilon > 0\) is small enough and \(0 < \eta \ll \epsilon\), we have a smooth (i.e. \(C^\infty\)) fibration:

\[\varphi_{\epsilon, \eta} : B_\epsilon \cap f^{-1}(D_\eta^*) \to D_\eta^*\]

induced by \(f\), where \(B_\epsilon\) is the closed ball of \(\mathbb{C}^N\) centered at \(x\) with radius \(\epsilon > 0\) and \(D_\eta^* = \{z \in \mathbb{C} | 0 < |z| \leq \eta\}\). We shall call this fibration the Milnor fibration of \(f\) at \(x\) (cf. [11] when \(X = \mathbb{C}^N\)).

The monodromy of this fibration is called the local monodromy of \(f\) at \(x\) (cf. [6]). We prove under the preceding hypothesis:

Theorem. (the Monodromy Theorem): The local monodromy of \(f\) at \(x\) is quasi-unipotent, i.e. its eigenvalues are roots of unity.

In [11] this theorem has been proved using the resolution of singularities. In [2], A. Grothendieck has given a proof which applies in the case we have a proper mapping \(f : X \to \mathbb{C}\); this proof actually uses the resolution of singularities and applies in any characteristic when there is a resolution of singularities. Another proof with a topological flavour,

---

*This article has been conceived during the stay of the author at the Mathematics Institute of the Vietnam Institute for Sciences at Hanoi and has been informally lectured at the Kyoto Symposium on Algebraic Geometry in January 1977.
but still using the resolution of singularities is given by A. Landman in [5].

In this paper we are giving a topological proof of the monodromy theorem which does not use the resolution of singularities and which gives a topological interpretation to the eigenvalues. The proof uses the notion of relative monodromy (cf. [6]) which is an avatar of the Lefschetz method for the study of the monodromy. Its strong interest comes from the use of a precise geometric description of the singularity. This leads to an interesting filtration of the Milnor fiber of $f$ at $x$.

I thank N. A’Campo for noticing a mistake in the original paper concerning the hypersurfaces. I thank K. Saito to have helped me to settle down correctly the proof. I thank R. Thom for the constant interest he showed in this paper.

1 Basic facts about the relative monodromy

Now we recall some results about the relative monodromy. cf. [6]. We still use the notations defined in the introduction. Let $z_1$ be a linear form of $\mathbb{C}^N$, say the first coordinate of $\mathbb{C}^N$. The restriction of $z_1$ to $X$ and $f$ defines a mapping $(z_1, f)$ of $X$ into $\mathbb{C}^2$. From [7] and [6], because $X - f^{-1}(0)$ is smooth, we have the following theorem:

**Theorem 1.1.** Suppose that $z_1 = 0$ be sufficiently general, then we have polydiscs $D \times P \subset \mathbb{C}^N$ centered at $x$ and $D \times D' \subset \mathbb{C}^2$ centered at $(z_1(x), 0)$, a curve $\Gamma \subset (D \times P) \cap X$ and a curve $\Delta \subset D \times D'$ such that:

1. the restriction $\Phi$ of $(z_1, f)$ to $(D \times P) \cap X$ is critical along $\Gamma$ outside $f^{-1}(0)$, moreover it induces a smooth fibration of $\Phi^{-1}(D \times D' - \Delta)$ onto $D \times D' - \Delta$;

2. $f$ induces a smooth fibration $\Phi^{-1}(D \times D' - D \times \{0\})$ onto $D' - \{0\}$ which is fiber isomorphic to the Milnor fibration of $f$ at $x$;

3. $f$ induces a smooth fibration of $(\{0\} \times P) \cap \Phi^{-1}(D \times D' - \{0\})$ onto $D' - \{0\}$ which is fiber isomorphic to the Milnor fibration of the restriction of $f$ to $X \cap \{z_1 = 0\}$ at $x$;
(4) for any \( x \in \Delta - \{0\} \) the fibers \( \Phi^{-1}(x) \) have only one quadratic ordinary singular point at \( y = \Gamma \cap \Phi^{-1}(x) \).

In [8] and [6] we have called \( \Gamma \) the polar curve of \( f \) relatively to \( z_1 = 0 \) and \( \Phi(\Gamma) = \Delta_0 \) its Cerf diagram. Notice that it may happen that \( \Delta = \Delta_0 \), but in general \( \Delta = \Delta_0 \cup (D \times \{0\}) \).

In [6] we have seen that in this situation we have defined a smooth mapping \( h \) of the Milnor fiber \( \Phi(D \times \{\eta\}) \) onto itself where \( \eta \in \partial D' \) which is a characteristic diffeomorphism of Milnor fibration of \( f \) at \( x \). Moreover \( h \) lifts a diffeomorphism \( \Psi \) of \( D \times \{\eta\} \) onto itself such that the following diagram is commutative:

\[
\begin{array}{ccc}
\Phi^{-1}(D \times \{\eta\}) & \xrightarrow{h} & \Phi^{-1}(D \times \{\eta\}) \\
\varphi \downarrow & & \varphi \downarrow \\
D \times \{\eta\} & \xrightarrow{\Psi} & D \times \{\eta\}
\end{array}
\]  

(1.2)

where \( \varphi \) is induced by \( \Phi \) and \( \Psi \) satisfies the following properties:

1. \( \Psi(0, \eta) = (0, \eta) \)
2. \( \Psi(D \times \{\eta\}) \cap \Delta = (D \times \{\eta\}) \cap \Delta \).

Further properties of \( \Psi \) will be given in the next paragraph. In [6] it has been seen that \( h \) induces a smooth mapping of \( \Phi^{-1}(0, \eta) \) onto itself which is a characteristic diffeomorphism of the Milnor fibration of the restriction of \( f \) to \( X \cap \{z_1 = 0\} \). Then \( h \) induces an automorphism of \( H_s(\Phi^{-1}(D \times \{\eta\}), \Phi^{-1}((0, \eta))) \) which defines the relative local monodromy of \( f \) at \( x \). From the fact that \( X - f^{-1}(0) \) is smooth and the (4) of the Theorem (1.1) cited above, a reasoning as in [8] leads to:

**Lemma 1.3.** \( H_k(\Phi^{-1}(D \times \{\eta\}), \Phi^{-1}((0, \eta))) = \begin{cases} 0 & \text{if } k \neq \dim_C f^{-1}(t) \\ \mathbb{Z}^r & \text{if } k = \dim_C f^{-1}(t) \end{cases} \) with \( t \) small enough and \( t \neq 0 \), and \( r \) equal to the number of points of \( \Delta \cap (D \times \{\eta\}) \) or \( \Gamma \cap \Phi^{-1}(D \times \{\eta\}) \).

Notice that \( \Gamma \) may be \( \emptyset \) and thus \( H_s(\Phi^{-1}(D \times \{\eta\}), \Phi^{-1}((0, \eta))) \) may entirely vanish.
Now we are going to give a more precise description of \( \Psi \) which will allow us to prove the monodromy theorem.

2 The Carrousel

We are going to recall the results of [6] and [7] which describe \( \Psi \).

Let

\[
\begin{align*}
\lambda &= t^r \\
z_1 &= \sum_{j \geq r_i} a_{ij} t^j \quad a_{ir_i} \neq 0
\end{align*}
\]  

(2.1)

be a parametrization of \( \Delta_i \).

Let us index the \( \Delta_1, i = 1, \ldots, k \), such that for any \( 1 \leq i \leq i_1 - 1 \), we have

\[
\begin{align*}
\frac{r_1}{r} &= \frac{r_i}{r} = \frac{m'_1}{n'_1} \quad \text{with} \quad (m'_1, n'_1) = 1 \\
a_{ir_1} &= a_{ir_i} = \alpha_1
\end{align*}
\]  

(2.2)

for any \( i \leq i \leq i_{l+1} - 1 = k \), we have

\[
\begin{align*}
\frac{r_{il}}{r} &= \frac{r_i}{r} = \frac{m'_l}{n'_l} \quad \text{with} \quad (m'_l, n'_l) = 1 \\
a_{ir_{il}} &= a_{ir_i} = \alpha_l
\end{align*}
\]

and moreover

\[
\frac{m'_1}{n'_1} \geq \frac{m'_2}{n'_2} \geq \ldots \geq \frac{m'_l}{n'_l}
\]

all couples \( \left( \frac{m'_i}{n'_i}, \alpha_i \right) \) are distinct and if \( \frac{m'_j}{n'_j} = \frac{m'_{j+1}}{n'_{j+1}} \), we have \( |\alpha_j| \leq |\alpha_{j+1}| \).

Let us call \( C_1, \ldots, C_l \) the curves defined by

\[
\begin{align*}
\lambda &= t^{n'_j} \\
z_1 &= \alpha_j \alpha^{m'_j} j = 1, \ldots, l.
\end{align*}
\]  

(2.3)
If $\eta$ is small enough, it is clear that the points of $(D \times \{\eta\}) \cap (\Delta_{ij} \cup \ldots \cup \Delta_{i+j+1-1})$ lie in a neighbourhood of $(D \times \{\eta\}) \cap C_j$. More precisely

**Lemma 2.4.** If $\eta$ is small enough, in $D \times \{\eta\}$ there are disjoint discs $\delta_{j\mu}(j = 1, \ldots, l$ and $\mu = 1, \ldots, n'_j)$ centered at the $n'_j$ points of $(D \times \{\eta\}) \cap C_j$, when $j = 1, \ldots, l$, such that

$$(D \times \{\eta\}) \cap (\Delta_{ij} \cup \ldots \cup \Delta_{i+j+1-1}) \subset \bigcup_{\mu=1}^{n'_j} \delta_{j\mu}.$$ 

Moreover the number of points of $\delta_{j\mu} \cap (\Delta_{ij} \cup \ldots \cup \Delta_{i+j+1-1})$ is the same for $\mu = 1, \ldots, n'_j$ and the $\delta_{j\mu}$ have the same radius for $\mu = 1, \ldots, n'_j$.

Now let us suppose that:

\[
\begin{array}{c}
\frac{m'_1}{n'_1} = \ldots = \frac{m'_{j_1-1}}{n'_{j_1-1}} \\
\frac{m'_{j_1}}{n'_{j_1}} = \ldots = \frac{m'_{j_2-1}}{n'_{j_2-1}} \\
\ldots \\
\frac{m'_{j_s}}{n'_{j_s}} = \ldots = \frac{m'_l}{n'_l}
\end{array}
\] (2.5)

and

\[
\frac{m'_1}{n'_1} > \frac{m'_{j_1}}{n'_{j_1}} > \ldots > \frac{m'_{j_s}}{n'_{j_s}}.
\]

**Lemma 2.6.** If $\eta$ is small enough, in $D \times \{\eta\}$ there are closed discs centered at $(0, \eta)$, say $D_1 \subset D'_1 \subset \ldots \subset D'_{s-1} \subset D_s \subset D$ such that

1) the interior $\overset{\circ}{D}_1$ contains the $\delta_{j\mu}$ with $j = 1, \ldots, j_1 - 1$ and $\mu = 1, \ldots, n'_j$;

2) the open annulus $\overset{\circ}{D}_2 - D'_1$ contains the $\delta_{j\mu}$ with $j = j_1, \ldots, j_2 - 1$ and $\mu = 1, \ldots, n'_j$;

\ldots\ldots\ldots
The Geometry of the Monodromy Theorem

s) the open annulus $\hat{D}_s - D'_{s-1}$ contains the $\delta_{j\mu}$ with $j = j_s, \ldots, l$ and $\mu = 1, \ldots, n'_j$.

Now we can summarize the properties of $\Psi$ (cf. [6] and [8]) as follows:

2.7

1) $\Psi$ is a smooth diffeomorphism of $D \times \{\eta\}$ onto itself;

2) its restriction to $D_1 - \bigcup (\bigcup_{\mu=1}^{\eta'} \delta_j)$ is a rotation of angle $2\pi \frac{m'_1}{n'_1}$;

3) its restriction to $(\hat{D}_s - D'_{s-1}) - \bigcup (\bigcup_{\mu=1}^{\eta'} \delta_j)$ is a rotation of angle $2\pi \frac{m'_{js}}{n'_{js}}$;

4) its restriction to each circle centered at $(0, \eta)$ and contained in $\hat{D}_i - D'_{i-1}$ and $D - D_s$ is a rotation.

The we define a class of smooth diffeomorphisms of a disc $D$ onto itself to which $\Psi$ will belong.

**Definition 2.8.** Any diffeomorphism of $D$ onto itself which maps the center of $D$ on itself, which has a fixed point $x \notin \partial D$ and the restriction of which is the identity on $\partial D$ is called a carrousel with one distinguished point $x \in \hat{D}$.

**Definition 2.9.** A roll is a diffeomorphism $\Psi$ of an open annulus $\hat{D} - D'$ onto itself such that:

1) there are circles $S_1, \ldots, S_m$ contained in $\hat{D} - D'$ and discs $\delta_{ij} \subset \hat{D} - D'(i = 1, \ldots, m, j = 1, \ldots, q)$ centered at points $x_{ij}$ (j = 1, \ldots, q) equidistributed on $S_i(i = 1, \ldots, m)$ and of the same radius for any fixed $i$;
2) there are the same number of distinguished points in each \( \delta_{ij} \) (\( j = 1, \ldots, q \)) for a given \( i \), such that \( \Psi \) maps \( \delta_{ij} \) onto \( \delta_{ij+1} \) for \( j = 1, \ldots, q^{-1} \) (resp. \( \delta_{iq} \) onto \( \delta_{i1} \)) and the distinguished points of \( \delta_{ij} \) onto those of \( \delta_{ij+1} \) for \( j = 1, \ldots, q^{-1} \) (resp. those of \( \delta_{iq} \) onto those of \( \delta_{i1} \));

3) the restriction of \( \Psi \) to \( \hat{D} - D' - \bigcup_{i,j} \delta_{ij} \) is a rotation of angle \( 2\pi\frac{p}{q} \), \((p,q) = 1\).

If \( \Psi \) is a roll, \( \Psi^q \) induces a diffeomorphism \( \Psi_{ij} \) of \( \delta_{ij} \) onto itself which maps the distinguished points of \( \delta_{ij} \) onto themselves. We shall call the diffeomorphisms \( \Psi_{ij} \) the distinguished diffeomorphisms of the roll.

We have defined a carrousel with one distinguished point, we suppose we have defined carrousels with \( n' \) distinguished points, \( 1 \leq n' < n \), we define what is a carrousel with \( n \) distinguished points.

**Definition 2.10.** A ‘carrousel with \( n \) distinguished points’ is a diffeomorphism \( \Psi \) of \( D \) onto itself such that:
1) there are discs $D_1 \subset D_1' \subset D_2 \subset \ldots \subset D_k \subset D$ such that the restriction $\Psi_i$ of $\Psi$ to $\hat{D}_i - D_{i-1}'$ is a roll;

2) the $n$ distinguished points of $\Psi$ are the distinguished points of the $\Psi_i$;

3) the distinguished diffeomorphisms of each roll are
   
   a) either carrousels with $n'$ distinguished with $1 \leq n' < n$;
   
   b) or $k = 1$ and the roll $\Psi_1$ has only one distinguished diffeomorphism which satisfies 1) and 2); then if it satisfies 3)-b) this process will stop after $l$ steps with carrousels with $n'$ distinguished points with $1 \leq n' < n$. Such a carrousel is called a carrousel which simplifies after $l$ steps.

Example. (cf. [6] and [7]).

Lemma 2.11. The smooth mapping $\Psi : D \times \{\eta\} \to D \times \{\eta\}$ of (2.7) is actually a carrousel the distinguished points of which are $(\Delta_1 \cup \ldots \cup \Delta_k) \cap (D \times \{\eta\})$. 
3 The Monodromy Theorem:

We can summarize the preceding results by

**Theorem 3.1.** \( \eta > 0 \) is small enough, there is a commutative diagram (cf. (1.2)):

\[
\begin{array}{ccc}
\Phi^{-1}(D \times \{\eta\}) & & \Phi^{-1}(D \times \{\eta\}) \\
\downarrow & & \downarrow \\
k \downarrow & & \downarrow \\
D \times \{\eta\} & \xrightarrow{\psi} & D \times \{\eta\}
\end{array}
\]

such that:

1) \( \Psi \) is a carrousel the distinguished points of which are \((D \times \{\eta\}) \cap \Delta;\)

2) \( h \) is a characteristic diffeomorphism of the Milnor fibration of \( f \) at \( x; \)

3) \( h \) induces a diffeomorphism of \( \Phi^{-1}(0, \eta) \) onto itself which is a characteristic diffeomorphism of the Milnor fibration of the restriction of \( f \) to \( X \cap \{z_1 = 0\} \) at \( x; \)

4) the fibers of \( \varphi \) over the distinguished points of \( \Psi \) are singular and have only one ordinary quadratic singular point, the other fibers of \( \varphi \) are smooth.

Moreover, it is clear that if \( \dim_C f^{-1}(t) = 0 \) when \( t \neq 0 \) is small enough, the monodromy theorem is true.

(H) *Let us assume it is true when \( 1 \leq \dim_C f^{-1}(t) < n. \)*

Suppose now that \( \dim_C f^{-1}(t) = n. \)

From the induction hypothesis we know that for any parametrization \( \pi : (C, 0) \rightarrow (C^2, 0) \) of a germ of curve \((C, 0)\) in \((C^2, 0)\), such that \((C, 0)\) does not lie inside \((C \times \{0\})\) the monodromy of the pullback \( f_\pi \) of \( \Phi \) is quasi-unipotent:

\[
\begin{array}{ccc}
X_\pi, 0 & \xrightarrow{f_\pi} & X, 0 \\
\downarrow \Phi & & \downarrow \\
(C, 0) & \xrightarrow{\pi} & (C^2, 0)
\end{array}
\]
Then we obtain:

**Lemma 3.2.** For any point \( x \in D_i - (\dot{D}_{i-1}' \cup \delta_{ijk}) \), \( h^{n'_{ji}} \) induces an automorphism of \( H_\ast(\Phi^{-1}(x)) \) which is quasi-unipotent.

**Proof.** Consider a curve \( C_x \) parametrized by

\[
\begin{align*}
\lambda &= t^{n'_{ji}} \\
z_0 &= \alpha(x) t^{m'_{ji}}
\end{align*}
\]

such that \( x \in C_x \). It is clear that such a curve exists and does not contain any point of \( \Delta \cap (D \times \{\eta\}) \) as

\[
C_x \cap (D \times \{\eta\}) = C_x \cap (D_i - (\dot{D}_{i-1}' \cup \delta_{ijk})).
\]

It is enough now to notice that \( \Psi \) induces a bijection of \( C_x \cap (D \times \{\eta\}) \) onto itself which is lifted in a characteristic diffeomorphism of the fibration \( \Phi^{-1}(C_x \cap (D \times \partial D')) \to \partial D' \) induced by \( f \). Finally the monodromy of this fibration is quasi-unipotent as its pull back by \((*)\) is quasi-unipotent according to the induction hypothesis.

Actually we have a more precise result which will allow us to prove the monodromy theorem by induction on the dimension of the fiber \( \square \)

**Lemma 3.3.** Let \( \Psi_{ijk} : \delta_{ijk} \to \delta_{ijk} \) a distinguished carrousel of the carrousel \( \Psi \). Let \( x \) be a point of \( \delta_{ijk} \to \Delta \) on which the action of \( \Psi_{ijk} \) is one of the rotations of this carrousel. Then there is a power \( h^q \) of \( h \) which induces a quasi-unipotent automorphism of \( H_\ast(\Phi^{-1}(x)) \). This property is true for the distinguished carrousels of \( \Psi_{ijk} \) and so on.

Let \( 2\pi p/q \) be the angle of the rotation induced by \( \Psi_{ijk} \) on \( x \). We may choose \( q \) multiple of \( n'_{ji} \). The proof is the same as the one of (3.2) by considering a curve parametrized by

\[
\begin{align*}
\lambda &= t^q \\
z_0 &= \alpha_t \frac{m'_{ji}}{n'_{ji}} + \beta(x) t^{m'_{ji}} + p
\end{align*}
\]
which goes through \( x \).

Because of the specific character of the points \( x \) which appear in (3.2) and (3.3) we shall call the points of \( D_i - (\hat{D}_{i-1} \cup \delta_{ijk}) \) the "rotating points" of the carrousel \( \Psi \). The distinguished carrousels of distinguished carrousels of \( \Psi \) and so on are called "successive distinguished carrousels of \( \Psi \). The rotating points of the successive distinguished carrousels of \( \Psi \) are called the "rolling points" of \( \Psi \).

Notice that if \( \Psi \) is a carrousel with one distinguished point the centre of \( D \) might be the only rolling point of \( \Psi \).

We can prove the theorem (3.1) now by using the following

**Theorem 3.3.** Let \( \varphi : X \to D \) be an analytic morphism of a connected analytic manifold \( X \) of dimension \( n \) onto a disc \( D \). Suppose that

1) there are a carrousel \( \Psi : D \to D \) and a smooth diffeomorphism \( h : X \to X \) such that:

\[
\begin{array}{c}
X \\
\varphi \\
\downarrow \\
D \\
\Psi \\
\downarrow \\
D \\
\h \\
X \\
\varphi \\
\downarrow \\
D \\
\Psi \\
\downarrow \\
D
\end{array}
\]

is commutative, \( \varphi \) is a smooth fibration outside the distinguished points of the carrousel \( \Psi \) and the fibers of \( \varphi \) over the distinguished points of \( \Psi \) have only one ordinary quadratic singular point;

2) for any rolling point \( x \) of \( \Psi \) the restriction to \( \varphi^{-1}(x) \) of some power \( h^q \) of \( q \) such that \( h^q(\varphi^{-1}(x)) = \varphi^{-1}(x) \) induces a quasi-unipotent automorphism of \( H_*(\varphi^{-1}(x)) \).

Then \( h \) induces an automorphism of \( H_*(X) \) which is quasi-unipotent.

**Proof of the Theorem (3.3).** We prove this theorem by induction on the number of distinguished points of the carrousel. If \( n = 1 \), the theorem is obvious as

\[
H_k(X, \varphi^{-1}(x)) = \begin{cases} 
0 \text{ if } k \neq n \\
\mathbb{Z} \text{ if } k = n 
\end{cases}
\]
if \( x \) is a point which is not the distinguished point of \( \Psi \), i.e. \( \varphi^{-1}(x) \) is smooth.

Then if, moreover, \( x \) is a rolling point such that there is an integer \( q \) such that \( \Psi^q(x) = x \), say \( x = 0 \) and then \( q = 1 \), then we have the exact sequence:

\[
0 \rightarrow H_n(X) \rightarrow H_n(X, \varphi^{-1}(0)) \rightarrow H_{n-1}(\varphi^{-1}(0)) \rightarrow H_{n-1}(X) \rightarrow 0
\]

and isomorphisms

\[
H_k(\varphi^{-1}(0)) \xrightarrow{\cong} H_k(X) \quad \text{for} \quad 0 \leq k \leq n - 2.
\]

As \( h \) induces quasi-unipotent automorphisms on \( H_n(X, \varphi^{-1}(0)) \) and on \( H_{n-1}(\varphi^{-1}(0)) \) from the commutativity of the corresponding diagrams, we obtain: the automorphism induced by \( h^q \) on \( H_*(X) \) is quasi-unipotent.

Suppose \( n > 1 \), and that for any \( 1 \leq n' < n \) the Theorem (3.3) is true for carrousels with \( n' \) distinguished points.

Now let us call \( U_i = \varphi^{-1}(D_i), i = 1, \ldots, k \) and \( U'_i = \varphi^{-1}(D'_i), i = 1, \ldots, k - 1 \).

Notice that \( U_i \subset U'_i \) is an equivalence of homotopy.

Then

**Lemma 3.4.** The diffeomorphism \( h \) induces a quasi-unipotent automorphism of \( H_*(U_i) \).

**Proof.** \( i = 1 \). If there is only one distinguished point of \( \Psi_1 \) which is therefore a carrousel with one distinguished point, we just apply the reasoning above and our lemma is proved.

If \( \Psi_1 \) has \( n_1 \) distinguished points, then there are three cases:

a) either there are strictly more than one distinguished diffeomorphism which is a carrousel with \( n' \) points, \( n' < n_1 \), thus with \( n' < n \);

b) either there is only one distinguished diffeomorphism which is a carrousel with \( n' \) points, \( n' = n_1 \) and \( n_1 < n \);
c) either there is only one distinguished diffeomorphism which is a
carrousel with \( n_1 = n \) points but this carrousel simplifies after \( k - 1 \)
steps.

We may consider the cases a), b) and c) together by doing the inductive hypothesis:

\((H')\) The Theorem (3.3) is true when \( \Psi \) is a carrousel with \( n' \) distin-
guished points and which simplifies after \( l \), steps with \( n' < n \) or \( n' = n \)
and \( l' < l \).

Now we suppose that \( \Psi \) is a carrousel with \( n \) distinguished points
and which simplifies after \( l \) steps.

Then the diffeomorphism \( h \) induces an automorphism of \( H_*(\varphi^{-1}(\delta_{1,jk})) \)
which is quasi-unipotent according to the induction hypothesis as we
have the commutative diagram.

\[
\begin{array}{ccc}
\varphi^{-1}(\delta_{1,jk}) & \xrightarrow{h_{1,jk}} & \varphi^{-1}(\delta_{1,jk}) \\
\downarrow \delta_{1,jk} & & \downarrow \delta_{1,jk} \\
\delta_{1,jk} & \xrightarrow{\Psi_{1,jk}} & \delta_{1,jk}
\end{array}
\]

where \( \Psi_{1,jk} \) is the distinguished carrousel of \( \Psi_1 \) induced by \( \Psi^{q_1}_{1,j} \) and \( h_{1,jk} \)
is induced by \( h^{q_1} \).

Notice that : \( U_1 = \varphi^{-1}(U_1 - \bigcup_{j,k} \delta_{1,jk}) \cup \varphi^{-1}(\delta_{1,jk}) \).

We denote : \( \varphi^{-1}(U_1 - \bigcup_{j,k} \delta_{1,jk}) = V_1 \).

We have : \( V_1 \cap (\bigcup_{j,k} \varphi^{-1}(\delta_{1,jk})) = \bigcup_{j,k} \varphi^{-1}(\partial_\delta \delta_{1,jk}) \).
We prove

**Lemma 3.5.** $h^q$ induces a quasi-unipotent automorphism of $H_*(V_1)$ and of $H_*(\partial \delta_{1jk})$.

Actually this lemma is a consequence of

**Lemma 3.6.** Let $\varphi : X \to Y$ be a smooth fibration of a smooth manifold $X$ onto a relatively compact manifold $Y$ and $\Psi : Y \to Y$ a mapping such that $\Psi^q = \text{Id} Y$ and $h : X \to X$ such that we have the commutative diagram:

$$
\begin{array}{ccc}
X & \xrightarrow{h} & X \\
\downarrow \varphi & & \downarrow \varphi \\
Y & \xrightarrow{\Psi} & Y
\end{array}
$$

Suppose that the restriction of $h^q$ to $\varphi^{-1}(x)$ for any $x \in Y$ induces a quasi-unipotent automorphism of $H_*(\varphi^{-1}(x))$, then $h$ induces a quasi-unipotent automorphism of $H_*(X)$.

**Proof.** Considering $\Psi^q$ and $h^q$ instead of $\Psi$ and $h$ we may suppose that $\psi = \text{Id} Y$. 

\[\square\]
Then our result follows from an obvious spectral sequence reasoning or we can prove it by considering a covering $U_1, \ldots, U_s$ of $Y$ by contractible open sets such that $U_i \cap U_j$ are contractible. Then prove by induction that the restriction of $h$ to $\varphi^{-1}(U_1 \cup \ldots \cup U_i)$, $i = 1, \ldots, s$ induces a quasi-unipotent automorphism of $H_*(\varphi^{-1}(U_1 \cup \ldots \cup U_i))$.

Now we have the Mayer-Vietoris sequence

$$
\rightarrow \bigoplus_{j,k} H_k(\partial \delta_{1,jk}) \rightarrow \bigoplus_{j,k} H_k(\delta_{1,jk}) \oplus H_k(V_1) \rightarrow H_k(U_1) \rightarrow .
$$

The actions of $h^{q_1}$ on $\bigoplus_{j,k} H_k(\partial \delta_{1,jk})$ and $H_k(V_1)$ are quasi-unipotent because the points of $\partial \delta_{1,jk}$ and $V_1$ are rolling points. Thus this comes from our hypothesis 2) in (3.3) and the Lemma (3.6).

**Thus we have proved** (3.4) **when** $i = 1$.

Let us suppose we have proved (3.4) for $1 \leq i < i_0$. We shall prove it for $H_*(U_{i_0})$. Notice that:

$$
U_{i_0} = U'_{i_0-1} U \varphi^{-1}(D_{i_0} - \mathring{D}'_{i_0-1}). \tag{3.7}
$$

As $U_{i_0-1} \subset U'_{i_0-1}$ is a homotopy equivalence, the action of $h$ on $H_*(U'_{i_0-1})$ is quasi-unipotent. From Lemma (3.6) and the hypothesis 2) of (3.3) we obtain that the action on $H_*(\varphi^{-1}(\partial D'_{i_0-1}))$ is quasi-unipotent. We obtain our result by using again the Mayer-Vietoris sequence coming from (3.7) if we prove that the action of $h$ on $H_*(\varphi^{-1}(D_{i_0} - \mathring{D}'_{i_0-1}))$ is quasi-unipotent.

Let $\Psi_{i_0,jk} : \delta_{i_0,jk} \rightarrow \delta_{i_0,jk}$ be a distinguished carrousel associated to the roll $\Psi_{i_0}$. From the inductive hypothesis $h^{q_{i_0}}$ induces a quasi-unipotent automorphism of $H_*(\varphi^{-1}(\delta_{i_0,jk}))$. The Lemma (3.6) applies to $\varphi^{-1}(D_{i_0} - (\mathring{D}'_{i_0-1} \cup \delta_{i_0,jk}))$ which is a smooth fibration onto $D_{i_0} - D'_{i_0-1} \cup \delta_{i_0,jk}$ by $\varphi$. Thus because of (3.6) and 2) of (3.3) $h^{q_{i_0}}$ induces a quasi-unipotent automorphism of $H_*(\varphi^{-1}(D_{i_0} - (D'_{i_0-1} \cup \delta_{i_0,jk})))$. For the same reason (application of the Lemma (3.6)), $h^{q_{i_0}}$ induces a quasi-unipotent automorphism of $H_*(\varphi^{-1}(\cup \partial \delta_{i_0,jk}))$. Using again the Mayer-Vietoris ar-
The Geometry of the Monodromy Theorem

argument, $h^{q_{i_0}}$, thus $h$ itself, induces a quasi-unipotent automorphism of $H_*(\varphi^{-1}(D_{i_0} - \hat{D}'_{i_0-1}))$.

Now our Theorem (3.3) is proved as $U_k \subset X$ is a homotopy equivalence, as $D - \hat{D}_k$ does not contain any critical values of $\varphi$.

**Corollary 3.8 (Monodromy theorem).** The local monodromy of $f$ at $x$ is quasi-unipotent.

**Conclusion.** The preceding proof has explicited a filtration of $H_*(F)$ where $F$ is the Milnor fibration and $F' = F \cap \{z_1 = 0\}$:

$$H_*(F') \subset H_*(U_1) \subset H_*(U_2) \subset \ldots \subset H_*(U_k) = H_*(F)$$

which is invariant under the action of the local monodromy.

One can prove that

$$H_*(F, F') \cong \bigoplus_{i=1}^{k} H_*(U_i, U_{i-1})$$

with $U_0 = F'$.

The relative monodromy on $H_*(F, F')$ is then the direct sum of the actions of $h$ on $H_*(U_i, U_{i-1})$. By excision it is clear that $H_*(\varphi^{-1}(D_i - \hat{D}'_{i-1}), \varphi^{-1}(\partial D'_{i-1}))$ is isomorphic to $H_*(U_i, U'_{i-1})$.

Now in the case of complex hypersurfaces of $\mathbb{C}^{n+1}$, one can prove that $H_n(\varphi^{-1}(\delta_{i|j})) = 0$. Using a Mayer-Vietoris type argument as in the proof of the Lemma (3.6) above, we obtain that the relative monodromy induces an automorphism of $H_n(U_i, U_{i-1})$ the eigenvalues of which are $p_i$-th power of the eigenvalues of the local monodromy of the restriction of $z_1$ to the hypersurface $f^{q_i} - z_1^{p_i} = 0$, where $p_i$ and $q_i$ are integers, $(p_i, q_i) = 1$ and $2\pi \frac{p_i}{q_i}$ is the rotation angle of the roll $\Psi_i$.

By a more precise study of this geometry this should lead to an exact knowledge of the eigenvalues of the local monodromy by induction on the dimension. As it is seen the rotation angles $2\pi \frac{p_i}{q_i}$ interferes in this study. We want to point out that the interest of these $\frac{p_i}{q_i}$ have been arisen algebraically by B. Teissier in [12] and [13] in the case when $f = 0$ is
a complex hypersurface with isolated singularity. In [10], M. Merle has computed these numbers in terms of Puiseux exponents of the curve when $n = 1$.

In fact it seems that one can likely study the Gauss-Manin connection of the singularity of $f$ at $x$ by using this geometry. This should lead to a relative Gauss-Manin connection. One expects a knowledge about the link between the roots of the $b$-polynomial (Bernstein polynomial) of $f$ and the eigenvalues of its local monodromy at $x$ as it has been done by B. Malgrange in [9]. This should give another proof of the rationality of the roots of the $b$-polynomial which does not use the resolution of the singularities of $f$ (cf. [4]).

References

THROUGHOUT THIS article, we shall mean by a ring a commutative ring with identity.

Roughly speaking, an integral domain which admits the Euclid algorithm is called a Euclid ring. But there are some distinctions among the ways conditioning the Euclid algorithm, and we want to discuss the subject. Since the Euclid algorithm can be observed independently of the property that the ring is an integral domain, we dare define a Euclid ring without assuming the integrity. Thus:

**Definition.** A ring $E$ is called a Euclid ring if there is a mapping $\rho$ of $E - \{0\}$ into a suitable well-ordered set $W$ so that it holds that if $a, b \in E$, $a \neq 0$, then there are $q, r \in E$ such that

$$b = aq + r, \quad \text{and either } \rho r < \rho a \quad \text{or} \quad r = 0. \quad (\ast)$$

In this case, we say also that $(E, W, \rho)$ is a Euclid ring.

Of course, main importance is in the case of a usual Euclid ring, for which we add the assumption:

(1) $E$ is an integral domain.

Now, the distinction of the definitions of a Euclid ring comes from whether or not we assume some of the following two conditions:

(2) If $b$ is a multiple of $a (a, b \in E, b \neq 0)$, then $\rho b \geq \rho a$.

(3) $W$ is isomorphic to the set $\mathbb{N}$ of natural numbers.
Our main results are the following:

**Theorem 1.2.** If \((E, W, \rho)\) is a Euclid ring, then there is a mapping \(\tau : E - \{0\} \to W\) such that \((E, W, \tau)\) is a Euclid ring satisfying the condition (2).

Thus, though (2) restricts the choice of the mapping \(\rho\), it does not restrict the class of Euclid rings.

**Theorem 2.3.** There is a Euclid ring \((E, W, \rho)\) such that (i) \(E\) is an integral domain and (ii) for any mapping \(\tau : E - \{0\} \to \mathbb{N}\), \((E, \mathbb{N}, \tau)\) cannot be a Euclid ring.

Thus, even in the case of integral domains, the condition (3) reduces the class of Euclid rings. As will be seen by Theorem 4.2, a structure theorem of a non-integral Euclid ring, there are easy examples of similar character if we do not assume \(E\) to be an integral domain. The existence of such an integral domain was asked by P. Samuel, About Euclidean Rings, *J. Algebra*, 19 (1971), who defined an Euclid ring without assuming integrity. Hiblot [C. R. Acad. Sc. Paris, 281 (22 Sept. 1975), ser. A] claimed an example, but his proof contains some errors.

In order to make this article to be self-contained, we repeat some of the results in the article of Samuel.

## 1 The condition (2).

A local principal ideal ring is either an Artin local ring or an integral domain. This means that if \(E\) is a principal ideal ring and if \(Q, Q'\) are mutually distinct primary components of the zero ideal, then there is no maximal ideal containing both of \(Q, Q'\). Thus:

**Lemma 1.1.** A principal ideal ring \(E\) is the direct sum of certain principal ideal rings \(E_1, \ldots, E_m\) such that each \(E_i\) is either an Artin local ring or an integral domain.

Now we prove:
Theorem 1.2. If \((E, W, \rho)\) is a Euclid ring, then there is a mapping \(\tau : E - \{0\} \to W\) such that \((E, W, \tau)\) is a Euclid ring satisfying the condition (2) (with \(\tau\) instead of \(\rho\)).

Proof. As is well known, a Euclid ring is a principal ideal ring. Applying Lemma 1.1 to \(E\), we obtain \(E, \ldots, E_m\). Let \(e_i\) be the identity of \(E_i\). Now, let \(U\) be the unit group of \(E\) and define \(\tau\) by:

\[
\tau a = \min\{\rho(au) | u \in U\}
\]

If \(a, b \in E\), \(a \neq 0\), then there are \(u \in U\) and \(q, r \in E\) such that \(\tau a = \rho(au)\), \(b = auq + r\), \(\rho r < \rho(au)\) or \(r = 0\). Thus \((E, W, \tau)\) is a Euclid ring. Let \(a\) be a non-zero element of \(E\), and set \(S = \{c \in E | ac \neq 0\}\). Choose \(d \in S\) so that \(\rho(ad) \leq \rho(ac)\) for any \(c \in S\). Then there are \(q, r \in E\) such that \(a = adq + r\), either \(\rho r < \rho(ad)\) or \(r = 0\). Since \(r\) is a multiple of \(a\), our choice of \(d\) shows that \(r = 0\). Thus \(a(1 - dq) = 0\). In each \(E_i, (ae_i)(e_i - de_iqe_i) = 0\). Therefore by the face that \(E_i\) is either a local ring or an integral domain with identity \(e_i\), we see that either \(ae_i = 0\) or \(de_i, qe_i\) are units in \(E_i\). If \(ae_i = 0\), then we may change \(d\) by adding any element of \(E_i\) and therefore there is a unit \(u\) such that \(ad = au\). By our assumption, \(\tau a = \tau(au)\). □

Note that we have proved that if \(b\) is a non-zero multiple of \(a\) and if \(\tau a = \tau b\), then \(b\) is an associate of \(a\) (i.e., an element of \(aU\)). Therefore if \(a, b \in E\) and if \(b\) is a proper multiple of \(a\) (i.e., \(b\) is a non-zero multiple of \(a\) and is not in \(aU\)), then \(\tau b > \tau a\). So we have

Corollary 1.3. If \((E, W, \rho)\) is a Euclid ring satisfying the condition (2), and if \(b\) is a proper multiple of \(a (a, b \in E)\), then \(\rho b > \rho a\).

2 An example

Before stating our example, we prove some preliminary results.

Lemma 2.1. Assume that \((A, M)\) is an Artin local ring, and \(B\) is an Artin ring containing \(A\), sharing the identity with \(A\) and is a finite \(A\)-module. Let \(A^*\) and \(B^*\) be the unit groups of \(A\) and \(B\), respectively. If \(B \neq A\), then \(\#(B^*/A^*) \geq \#(A/M)\).

*If \(M\) is a set, \(\#(M)\) denotes the cardinality of \(M\).*
Proof. First we consider the case where $B$ is not a local ring. Let $J$ be the radical of $B$ and consider the natural homomorphism $\varphi : B \to B/J$. The groups $B^*$, $A^*$ are mapped surjectively to the unit groups of $\varphi B$, $\varphi A$, respectively, and therefore we may assume that $J = 0$. Then $B$ is the direct sum of fields $B_1, \ldots, B_s(s \geq 2)$. Since each $B_i$ contains $Ae_i$ ($e_i$ being the identity of $B_i$), we see the assertion easily in this case.

Assume next that $(B, N)$ is a local ring. If $B/N \neq A/M$, then by taking an element $e$ of $B$ such that $(e \mod N) \notin A/M$ and considering cosets of $l + ue(u \in A^*)$, we see the assertion in this case. If $B/N = A/M$, then $N = MB$ by the lemma of Krull-Azumaya. Therefore, taking an element $e$ of $N$ outside of $MB$, we prove the assertion similarly.

Next we introduce the notion of a canonical structure of a Euclid ring. First we make a well-ordered set $W$ to be canonical. Namely, we take the ordinal number $v$ which represents the order-type of $W$; $W$ is isomorphic to the set $W'$ of ordinal numbers smaller than $v$. Therefore we identify $W$ with $W'$ at this step. We set $W'' = W \cup \{v\}$. Note that the least member of $W'$ is 0 (order-type of the empty set). Now let $E$ be an arbitrary ring. For every $\mu \in W''$, we define $R_\mu$ and $S_\mu$ inductively as follows: (i) $R_0$ is the unit group, (ii) if $\mu \in W''$ and if $R_\lambda$ are defined for all $\lambda < \mu$, then $S_\mu = \{0\} \cup \bigcup_{\lambda < \mu} R_\lambda$ and $R_\mu = \{a \in E - S_\mu| \text{ for any } b \in E,\}$ there are $q, r \in E$ such that $b = aq + r, r \in S_\mu\}$. Now, our definition of a Euclid ring shows the following fact:

**Lemma 2.2.** There is a mapping $\rho : E - \{0\} \to W$ such that $(E, W, \rho)$ is a Euclid ring if and only if $S_\nu = E$. In this case, $(E, W, \tau)$ is a Euclid ring with $\tau$ such that $\tau x = \mu$ if and only if $x \in R_\mu$. Furthermore if $x \in E - \{0\}$, then $\tau x \leq \rho x$.

Of course, $W$ may be too big. The smallest possible one is $W^* = \tau(E - \{0\})$. This $(E, W^*, \tau)$ is called the canonical structure of the Euclid ring $E$.

Now we come to the construction of a Euclid integral domain by which the condition (3) cannot be satisfied.

Consider a set of algebraically independent elements $X_t$ indexed by
the set $\mathbb{R}$ of real numbers and we set $A = P_S$ where $P$ is the polynomial ring in these $X_i$ over the ring $\mathbb{Z}$ of rational integers and $S = \{f \in P| \text{ coefficients of } f \text{ have no proper common factor }\}$. Then every element $a$ of $A$ is expressed in the form $qs$ with $s$ in the multiplicative group generated by $S$ and $q$ a natural number or zero. This $q$ is uniquely determined by $a$, called the absolute value of $a$ and denoted by $|a|$.

We order prime numbers and denote them by $p_1, p_2, \ldots, (p_1 < p_2 < \ldots)$. For each $n \in \mathbb{N}$, we take natural numbers $a_n$ and $e_{in}$ (for $i = 1, 2, \ldots, n$) and also elements $b_0, b_n, b_n^*$ as follows:

(i) Every $e_{in}$ is a multiple of $P_i$.

(ii) $a_n = \prod_i p_i^{e_{in}}, b_0 = 1, b_n = \prod_{i \leq n} a_i$ and $b_n^* = \sum_{i = 0}^{n-1} b_i x_i$.

Next we consider the polynomial ring $K[T]$ in one variable $T$ over the field $K$ of quotients of $A$. In this ring, we define $T_n$ by $T = T_0 = b_n^* + b_n T_n$ and we set $B_n = A[T_n], B = \cup_n B_n$. Note that $T_n = X_n + a_{n+1} T_{n+1}$.

Let $S^*$ be the multiplicatively closed subset generated by $T_0, T_1, \ldots, T_n, \ldots$ and set $E = B S^*$. Now we claim:

**Theorem 2.3.** The integral domain $E$ is a Euclid ring, but, not under the condition (3).

The proof proceeds stepwise. First consider $f(T) = d_0 + d_1 T + \ldots + d_s T^s \in A[T](d_i \in A, d_s \neq 0)$. For each $m \in \mathbb{N}$, $f$ is expressed as the product of a natural number $c_m$ and a primitive polynomial $f_m$ in $T_m$ over $A$. Obviously $c_m$ divides $c_{m+1}$. We want to show:

**Lemma 2.4.** There is a natural number $m$ such that for every natural number $n \geq m$, it holds that (i) $c_n = c_m$ and (ii) the constant term of $f_n$ is a unit in $A$.

**Proof.** Multiplying some element of $S$, we may assume that all $d_i$ are in $P$. Then we can take a natural number $m$ such that there is no $X_t$, with $t \geq m - 1$, appearing in some $d_i$. Then we consider $f = c_{m-1} f_{m-1}$, $f_{m-1} = e_0 + e_1 T_{m-1} + \ldots + e_s T_{m-1}^s$. Then the constant term of $f$ in its expression as a polynomial in $T_m$ is $c_{m-1} f_{m-1}(X_{m-1})$ because $T_{m-1}$ =
$X_{m-1} + a_m T_m$. Since $f_{m-1}(T_{m-1})$ is primitive and since $X_{m-1}$ does not appear in the coefficients, we see that $f_{m-1}(X_{m-1}) \in S$. Thus this $m$ is the required natural number.

$f_m$ obtained above enjoys the properties that (i) it is a primitive polynomial in some $T_m$ over $A$ and (ii) for every natural number $n$ not smaller than $m$, the constant term of $f_m$ as a polynomial in $T_n$ over $A$ is a unit in $A$. Such an element of $B$ is called a primitive element of $B$.

Lemma 2.4 can be applied to any non-zero element $f$ of $K[T]$, and $f = cf_m$ with a positive rational number $c$ and a primitive element $f_m$. This $c$ is uniquely determined by $f$ and is called the content of $f$. Note the $f \in B$ if and only if the content is a natural number. Note also that $T_n$ are all primitive. □

**Lemma 2.5.** $B$ is a principal ideal domain. As ideal is maximal if and only if it is generated either by some $p_i (i \in \mathbb{N})$ or by a primitive element $f$ in $B$ which is irreducible and of positive degree as an element of $K[T]$. The unit group of $B$ is the group generated by $S$ and therefore every residue class of $B/p_iB$ is represented either by 0 or a unit.

**Proof.** The last half is obvious. As for the first half, similar statement holds for every $B_m$ and a prime element $f$ in $B_m$ is not a prime element in $B_{m+1}$ if and only if $f$ is a primitive polynomial in $T_m$ but not in $T_{m+1}$. □

**Corollary 2.6.** $E$ is a principal ideal domain and the unit group of $E$ is generated by $SS^*$. If $f \in E - \{0\}$, then with some $s \in S^*$, it holds that $sf \in B$ and we can apply the factorization given in Lemma 2.5 to $sf$ and we obtain $sf = cf_m$ with content $c$ and a primitive element $f_m$. $f_m$ may contain some factors which are in $S^*$; taking out all such factors, we have the following factorization:

$$f = cpu;$$

where $c$ is the content, $p$ is primitive and having no factor in $S^*$ and $u$ a unit in $E$.

These factors are uniquely determined by $f$ (as for $p$, $u$, we observe them within unit factors in $A$) and therefore we denote them by $c(f)$, $p(f)$, $u(f)$, respectively, from now on.
Now we consider \( W = N \times N \) (with lexicographical order), and we define a mapping \( \rho : E - \{0\} \rightarrow W \) by \( \rho f = (1 + \deg p(f), c(f)) \).

We claim:

**Lemma 2.7.** \((E, W, \rho)\) is a Euclid ring.

**Proof.** Let \( f, g \) be non-zero elements of \( E \) and we want to show the existence of \( q, r \in E \) such that \( g = fq + r \) and either \( r = 0 \) or \( \rho r < \rho f \).

Since unit factors of \( f, g \) can be disregarded (cf. the proof of Theorem 1.2), we may assume that \( f = c(f)p(f), g = c(g)p(g) \). We use an induction on \( \rho g \). If \( \rho g < \rho f \), then \( q = 0, r = g \). So we assume that \( \rho g \geq \rho f \). Then either (i) \( \deg g > \deg f \) or (ii) \( \deg g = \deg f \) and \( c(g) \geq c(f) \).

In the case (i), if we express \( f \) and \( g \) as polynomials in \( T_m \) with sufficiently large \( m \), then the coefficient of the highest degree term in \( f \) divides that of \( g \), and we can reduce to the case where \( \deg g \) is lower than before. Consider the case (ii). In \( B_m \) with sufficiently large \( m \), the constant terms of \( f, g \) are \( c(f)\)-unit, \( c(g)\)-unit. Therefore, by some \( q \) which is a unit in \( A \), the constant term of \( r \) has absolute value \( c(g) - c(f) \).

If \( c(f) \neq c(g) \), then \( \deg r \leq \deg f \) and \( c(r) < c(g) \), and this case is finished by our induction. If \( c(f) = c(g) \), then since \( T_m \) is a unit in \( E \), we have \( \deg p(r) < \deg p(f) \).

We consider the canonical structure \((E, W', \tau)\) of the Euclid ring \( E \).

In order to prove Theorem 2.3, it suffices to show:

**Proposition 2.8.** \( W' \simeq W = N \times N \).

In order to prove this, we adapt symbols \( R_\mu, S_\mu \) as in the definition of a canonical structure. So, \( R_0 \) is the unit group of \( E \). We prove the assertion stepwise.

(i) **If** \( n \) **is a natural number, then** \( R_n = \bigcup mR_0 \) **where** \( m \) **runs through** \( M_n = \{\pi_{p_i}^{e_i}|\sum e_i = n (e_i \geq 0)\} \).

**Proof.** In proving (i), we use induction arguments on \( n \). First note that every prime number is in \( R_1 \) in view of the last half of Lemma 2.5. Note also that if \( f(\in E - \{0\}) \) has a proper factor which is not in \( S_n \) then \( f \)
cannot be in $R_n$ in view of Corollary 1.3. By induction, no element of $M_n$ is in $S_n$. If $m \in M_n$, then in $E/mE$, an element $f$ such that $c(f)$ is coprime to $m$ is represented by a unit. Therefore, in general, an arbitrary element $f$ is congruent to an element of the form $d \cdot \text{unit}$ with $d = (\text{G.C.M. of } m \text{ and } c(f))$ and we see that $m \in R_n$. Thus $\bigcup_{m \in M_n} mR_0 \subseteq R_n$. Conversely, assume that $f \in R_n$. We may assume that $f = c(f)p(f)$. If $f = c(f)\cdot \text{unit}$, then the observation above and Corollary 1.3 imply that $c(f) \in M_n$. In order to show that $f = c(f)\cdot \text{unit}$, it suffices to show that if $f$ is a prime element of $E$ such that $f = p(f)$, then $f \notin R_n$ (by virtue of Corollary 1.3). Assume first that $\deg f = 1$. Then $f = d_0 + d_1 T_m$ with sufficiently large natural number $m(d_i \in A, |d_0| = 1)$. Then in $E/fE$, by our choice of $a_n$, we see that every sufficiently large prime number $q$ appears as a factor of a (unit in $E \bmod f$) only in a power of $q^q$. Thus $q$ appears as a factor of residue classes of elements of $S_n - \{0\}$ only in the form $q^{q-t}$ with $t$ such that $0 \leq t < n$. Therefore $f \notin R_n$. If $\deg f > 1$, then Lemma 2.1 implies that $f \notin R_n$.

As a consequence, we have:

(ii) $S_\omega = \bigcup uA$, where $\omega$ denotes the ordinal number corresponding to $\mathbb{N}$, and $u$ runs through the multiplicative group generated by $T_0, T_1, \ldots$.

(iii) For $n \in \mathbb{N}$ and $m \in \mathbb{N} \cup \{0\}$, it holds that

$$R_{n\omega + m} = \{f \in E - \{0\} \mid \deg p(f) = n, c(f) \in R_m\}.$$ 

Proof. By induction, $S_{n\omega} = \{0\} \cup (\cup fR_0)$ where $f$ runs through $F_n = \{f \in E \mid \deg p(f) < n\}$. Therefore, if $f$ is primitive and if $\deg p(f) = n$, then our proof of Lemma 2.7 shows that $f \in R_{n\omega}$. Conversely, if $f \in R_{n\omega}$, then $\deg p(f) \geq n$; if $\deg p(f) > n$, then our method in proving Lemma 2.1 shows that $f \notin R_{n\omega}$. If $c(f) \neq 1$, then Corollary 1.3 shows that $f \notin R_{n\omega}$. Thus we proved the case where $m = 0$. For $m > 0$, our proof (i) above is adapted and we complete the proof.

Now, this (iii) completes the proof of Proposition 2.8.
3 An operation on ordinal numbers

For each ordinal number \( \alpha \), we denote by \( W_\alpha \) the set of ordinal numbers \( \beta \) such that \( \beta < \alpha \). For a given cardinality \( b \), we denote by \( W_b \) the set of ordinal numbers \( \alpha \) such that \( \#(W_\alpha) < b \). Note that \( \#(W_b) = b \) and the ordinal number representing the order-type of \( W_b \) is the beginning ordinal number for the cardinality \( b \) in case \( b \) is an infinite cardinality.

Assuming that \( b \) is an infinite cardinality, we define an operation \(*\) on \( W_b \) by the following properties:

(i) \( \alpha \ast \beta = \beta \ast \alpha \),  
(ii) \( 0 \ast 0 = 0 \),  
(iii) \( (\alpha + 1) \ast \beta = (\alpha \ast \beta) + 1 \)  
(iv) if \( (\alpha, \beta) \neq (0, 0) \), then \( \alpha \ast \beta = \sup(\{\alpha \ast \beta' + 1| \beta' < \beta \} \cup \{\alpha' \ast \beta + 1| \alpha' < \alpha \}) \).

One sees easily that this \(*\) is well defined by these requirements, if we allow \( \alpha \ast \beta \) to be in a bigger set of ordinal numbers, though we shall show that \( \alpha \ast \beta \) belongs to \( W_b \) in Proposition 3.1 below. We shall call \(*\) maximal addition; \( \alpha \ast \beta \) is called the maximal sum of \( \alpha \) and \( \beta \).

The first remark is that \( \alpha \ast \beta \) is independent of \( W_b \) containing \( \alpha, \beta \) because of our definition.

We give further results on computing the value of maximal sums. From now on, Greek letters will denote ordinal numbers belonging to \( W_b \).

**Proposition 3.1.**  
(i) \( W_b \ast W_b = W_b \).  
(ii) \( \alpha \ast 0 = \alpha \).  
(iii) If \( m, n \) are finite, then \( (\alpha + m)(\beta + n) = (\alpha \ast \beta) + m + n \).  
(iv) If \( \alpha < \alpha' \), then \( \alpha \ast \beta < \alpha' \ast \beta \).

**Proof.** (ii) \sim (iv) are obvious by the definition. By (ii), we see that \( W_b \subseteq W_b \ast W_b \). By our definition, if \( \alpha, \beta \in W_b \), then \( W_{\alpha \ast \beta} \subseteq (W_\alpha \cup \{\alpha\}) \ast (W_\beta \cup \{\beta\}) \). Therefore \( \#(W_{\alpha \ast \beta}) \leq \#(W_\alpha \cup \{\alpha\}) \times \#(W_\beta \cup \{\beta\}) < b \). Thus \( W_{\alpha \ast \beta} \subseteq W_b \) and \( \alpha \ast \beta \in W_b \).

\[\text{†} \text{One can prove easily by virtue of Theorem 3.4 below that } \alpha \ast \beta \text{ is the largest among ordinal numbers which can be obtained in the form } \alpha_1 + \beta_1 + \ldots + \alpha_s + \beta_s \text{ with } \alpha_i, \beta_i \text{ such that } \alpha = \alpha_1 + \ldots + \alpha_s, \beta = \beta_1 + \ldots \beta_s.\]
(iii) above shows that in order to compute the value of $\alpha \ast \beta$, it is essential to know the value in the case where $\alpha, \beta$ are limit ordinal numbers, and let us investigate the case.

For a limit ordinal number $\lambda$, we consider $\Gamma_{\gamma, \lambda} = \{\mu \in W_b | \gamma < \mu < \lambda\}$ for every $\gamma < \lambda$ and let $\tau_\lambda$ be $\min \{\text{ordinal number representing the order-type of } \Gamma_{\gamma, \lambda} | \gamma < \lambda\}$. We call $\tau_\lambda$ the weight of $\lambda$, and the symbol $\tau$ will maintain its meaning in this section.

**Lemma 3.2.**

(i) If $\lambda$ is the beginning ordinal number for an infinite cardinality, then the weight of $\lambda$ is $\lambda$ itself.

(ii) If $\lambda$ is a limit ordinal number, then $\alpha + \lambda$ is also a limit ordinal number and $\tau_\lambda = \tau_{\alpha + \lambda}$.

(iii) If $\alpha = \tau_\lambda$ for some $\lambda$, then $\tau_\alpha = \alpha$.

Proof is easy and we omit it.

**Theorem 3.3.** Let $\alpha$ be an infinite ordinal number. Then the set $\Gamma = \{\tau_\lambda | \text{limit ordinal } \lambda \leq \alpha\}$ has a maximal member, say $\delta$, and $\tau_\delta = \delta$.

Furthermore, $M = \{\beta | \text{limit ordinal } \beta \leq \alpha, \tau_\beta = \delta\}$ is a finite set and $\delta$ is the smallest member in $M$.

The maximal member of $M$ is called the deepest limit ordinal number in $\alpha$.

Proof. Consider $\delta = \sup \Gamma$. If $\tau_\delta < \delta$, then there is a $\gamma$ smaller than $\delta$ such that the order-type of $\Gamma_{\gamma, \delta}$ is smaller than $\delta$. Then, with $\Gamma' = \{\tau_\beta \in \Gamma | \tau_\beta > \gamma\}$, we have $\delta = \sup \Gamma = \sup \Gamma' < \delta$, a contradiction. Thus $\delta = \tau_\delta$ and $\delta$ is the smallest member in $M$. If $M$ were infinite, then we have an ascending chain $\delta = \beta_0 < \beta_1 < \ldots < \beta_n < \ldots$ in $M$. Let $\mu = \sup_{n \in \mathbb{N}} \beta_n$. For any $\epsilon < \mu$, $\Gamma_{\epsilon, \mu}$ contains infinitely many $\beta_i$ which are in $M$; for $\epsilon' < \delta$, $\Gamma_{\epsilon', \mu}$ does not contain any member of $M$. Thus $\tau_\delta < \tau_\mu$, a contradiction. \qed

Maximal sums can be computed making use of the following:

**Theorem 3.4.** For infinite ordinal numbers $\alpha, \beta$, let $\delta_\alpha, \delta_\beta$ be the deepest limit ordinal numbers in $\alpha, \beta$, respectively.
Assume that $\tau_\delta \geq \tau_\beta$. Write $\alpha = \delta + \alpha', \beta = \delta + \beta'$. Then

(i) $\alpha \ast \beta = \delta + (\beta \ast \alpha')$,

(ii) If $\tau_\delta = \tau_\beta$, then $\alpha \ast \beta = (\delta + \delta) + (\alpha' \ast \beta')$.

Thus the computation can be reduced to the case where $\tau_\delta, \tau_\beta$ are smaller.

Proof. (ii) follows easily from (i), and it suffices to prove (i). We use an induction on $(\alpha, \beta)$; namely, we assume the validity of (i) for $(\alpha'', \beta'')$ such that $\alpha'' \leq \alpha, \beta'' \leq \beta, (\alpha'', \beta'') \neq (\alpha, \beta)$. If $\alpha > \delta, \beta > \delta$, then (i) is shown easily by induction hypothesis. The most important case is the case where $\alpha = \tau_\delta, \beta = \tau_\delta$. By induction, if $\beta'' < \beta$, then $\alpha \ast \beta'' = \alpha + \beta''$. If $\tau_\delta = \tau_\delta'$, then by the symmetry, we have $\alpha + \beta = \alpha \ast \beta$. If $\tau_\delta > \tau_\delta'$ and if $\alpha'' < \alpha$, then $\alpha'' \ast \beta < \tau_\delta$ by induction. Therefore $\alpha \ast \beta = \alpha + \beta$ in this case. The remaining case can be proved similarly. 

Corollary 3.5. Assume that $\alpha, \beta$ are limit ordinal numbers and that $\tau_\alpha \geq \tau_\beta$. Then $\alpha \ast \beta = \sup\{\alpha \ast \beta' | \beta' < \beta\}$ and $\tau_{\alpha \ast \beta} = \tau_\beta$.

Theorem 3.6. The maximal addition satisfies the associativity. Namely, $(\alpha \ast \beta) \ast \gamma = \alpha \ast (\beta \ast \gamma)$.

Proof. We use induction on $(\alpha, \beta, \gamma)$. If some of $\alpha, \beta, \gamma$ is not a limit ordinal number, the assertion is obvious by induction and by (iii) in the definition. If all of $\alpha, \beta, \gamma$ are limit ordinal numbers, then we prove the assertion easily by induction and by Corollary 3.5 above.

4 Structure of generalized Euclid rings

We maintain the notation of §3 except for $\rho, \rho', \rho_i, \varphi$ (which are mappings) and $W_i(i = 1, \ldots, s)$.

In this section, we want to show the following three theorems.
Theorem 4.1. Assume that a ring $E$ is the direct sum of rings $E_1, \ldots, E_s$. Then $E$ is a Euclid ring if and only if every $E_i$ is a Euclid ring. Consequently, a Euclid ring is the direct sum of Euclid rings $E_i, \ldots, E_s$ such that each $E_i$ is either an integral domain or an Artin local ring.

Theorem 4.2. Assume that $(E_i, W_i, \rho_i)(i = 1, \ldots, s; W_i \subset W_b$ with a sufficiently large cardinality $b)$ are Euclid rings and let $\lambda_i$ be the ordinal number representing the ordertype of $W_i$. Extend $\rho_i$ so that $\rho_i0 = \lambda_i$ and define $\rho : E = E_1 \oplus \ldots \oplus E_s \to W_{\mu+1}$ with $\mu = \lambda_1 \ast \ldots \ast \lambda_s$ by:

$$\rho(a_1 + \ldots + a_s) = (\rho_1a_1) \ast \ldots \ast (\rho_s a_s) \quad (a_i \in E_i).$$

Then $(E, W_\mu, \rho)$ is a Euclid ring.

If every $(E_i, W_i, \rho_i)$ is the canonical structure of $E_i$, then $(E, W_\mu, \rho)$ is the canonical structure of $E$.

Theorem 4.3. If $E$ is a Euclid ring, then (i) a ring which is a homomorphic image of $E$ is a Euclid ring and (ii) any ring of quotients of $E$ is a Euclid ring.

As for the proof of Theorem 4.1, the if part follows from Theorem 4.2, its only if part follows from Theorem 4.3 (i) and its last part follows from Lemma 1.1.

Theorem 4.2 follows from the definition of maximal addition, noting that the condition (*) in the definition of a Euclid ring is equivalent to the following:

(*) If $a, b \in E$, $a \neq 0$, then there are $q, r \in E$ such that $b = aq + r$, and $\rho r < \rho a$ or $r = a$.

Theorem 4.3 (i) follows from:

Proposition 4.4. Let $(E, W, \rho)$ be a Euclid ring. If $\varphi : E \to E'$ is a surjective ring homomorphism, then $(E', W, \rho')$ is a Euclid ring with $\rho'$ defined by:

$$\rho' x = \min \{ \rho y | \varphi y = x \}.$$

Proof. Assume that $a', b' \in E'$, $a' \neq 0$. Take $a, b \in E$ so that $\varphi a = a'$, $\rho a = \rho' a'$, $\varphi b = b'$. Then there are $q, r \in E$ such that $b = aq + r$, either $\rho r < \rho a$ or $r = a$. Then $b' = a'(\varphi q) + \varphi r$, either $\rho'(\varphi r) \leq \rho r < \rho a = \rho' a'$ or $\varphi r = 0$. \qed
Theorem 4.3(ii) follows from:

**Proposition 4.5.** Let \((E, W, \rho)\) be a Euclid ring and let \(S\) be a multiplicatively closed subset of \(E\) not containing \(0\). Then \((E_s, W, \rho')\) is a Euclid ring with \(\rho'\) defined by:

\[
\rho' x = \min \{ \rho y | y \in E, \text{there are } s, s' \in S, y s / s' = x \}.
\]

This can be proved quite similarly to the proof of Theorem 1.2.

In closing this article, the writer likes to remark that:

Although, in order to state the condition (*) in the definition of a Euclid ring, it is natural to extend \(\rho\) so that \(\rho 0 < \rho a\) for any \(a \neq 0\), in view of Theorem 4.2, Proposition 4.4 etc., the writer feels it to be more natural to extend \(\rho\) so that \(\rho 0 > \rho a\) for any \(a \neq 0\).
Principal Bundles on Affine Space

By M.S. Raghunathan

1 Introduction

The affirmative answer to Serre’s question on vector bundles on an affine space (due to Quillen [10] and Sublin) leads one to pose the following question (*):

Let \( k \) be a field and \( A^n_k = \text{Spec } k[X_1, \ldots, X_n] \to \text{Spec } k \) the affine space of dimension \( n \) over \( k \). Let \( G \) be an affine group scheme (of finite type) over \( k \) and \( P \) a principal \( G \)-bundle over \( A^n_k \). Is \( P \) then isomorphic to a bundle of the form \( P' \ox_k A^n_k \) where \( P' \) is a principal homogeneous space over \( k \).

(By a principal \( G \)-bundle \( P \) over a scheme \( X \) we mean a scheme \( p : P \to X \) over \( X \) together with a right action \( m : P \times G \to P \) such that the diagram

\[
\begin{array}{ccc}
P \times G & \xrightarrow{m} & P \\
\pi \downarrow & & \downarrow p \\
P & \xrightarrow{p} & X
\end{array}
\]

is commutative and the induced morphism

\[ P \times G \to P \times_X P \]

is an isomorphism. (It is known that with this definition, there exists for every point \( p \in \bar{X} = X \ox_k \bar{k} \), \( \bar{k} \) an algebraic closure of \( k \), a neighbourhood \( U \) of \( p \) and an etale morphism \( q : \bar{U} \to U \) such that \( \bar{U} \times_{\bar{X}} \bar{P} \) (\( \bar{P} = \bar{P} \ox_k \bar{k} \)) is isomorphic as a \( G \) space to \( \bar{U} \times_{\text{Spec } k} G \)).
The immediate expectation that Quillen’s theorem would generalise to any reductive group turns out to be false: Ojanguran and Sridharan \[8a\] and Parimala and Sridharan \[8b\] have results which show that the answer to the question is in general in the negative. Specifically in \[8a\] it is shown that when \(G\) is the group of norm 1 elements in a noncommutative division algebra over \(k\), there exist \(G\)-bundles over \(A_k^2\) which are not obtained by base change. When \(k = \mathbb{R}\) in \[8b\] it is shown that there are infinitely many inequivalent bundles on \(A_R^2\) which are not obtained by a base change from \(\mathbb{R}\). Using this, one can also show (see Parimala \[9\] where the case \(SO(4)\) over \(\mathbb{R}\) is dealt with) (*) has a negative answer for \(SO(3)\) and \(SO(4)\) over \(\mathbb{R}\). These examples suggested that one should look for an affirmative answer to (*) only under further restrictions on \(k\).

H. Bass \[1\] proved that if \(k\) is algebraically closed and of characteristic \(\neq 2\) and \(n = 2\), (*) has an affirmative answer for \(G = SO(n)\) the present work began in fact with providing an alternative (and more direct) proof for Bass’s theorem.

Before we can describe the results of the present work—which is mainly concerned with the case \(n \geq 2\) - we need to briefly outline the situation in the case of the affine line over \(k\). For the sake of brevity in later formulations we make the following:

**Definition.** A group \(G\) (over \(k\)) is ‘acceptable’ if for every extension \(L \supset k\), any principal \(G \otimes_k L\)-bundle over \(\text{Spec } L[X]\) is obtained from a bundle on \(\text{Spec } L\) by the base change \(L \to L[X]\).

\(G\) is known to be acceptable in the following cases:

(i) \(\text{Char } k = 0\), \(G\) any group. This is a recent result due to A. Ramanathan and the author \[11\].

(ii) \(G = 0(n)\) (hence also \(SO(n)\)), \(\text{Char } k \neq 2\) (Harder; see \[6a\])

(iii) \(G = SL(n), GL(n)\) or \(Sp(n)\) (\(k\) arbitrary): these cases are obvious.

(iv) \(G\) simply connected of inner-type \(A_n\): this follows from the fact that the projective modules over \(D[X]\), \(D\) a division algebra, are free (see for instance \[15\], p. 202).
(v) $G$ simply connected of classical type and $\text{Char} \ k$ ‘good’ for $G(\text{Char} \ k > 5$ is good for all $G$, (see [11]).

(vi) $G$ a torus of any semisimple group of inner type $A_n$ or a spin group: this follows from the earlier mentioned results and some Galois cohomology arguments. For more details see [11].

We expect the following to hold.

**Conjecture.** Any smooth simply ‘connected’ reductive group is acceptable.

(The assumption of connectedness is evidently essential in view of the existence of Artin Schrier extensions.)

After this discussion we can now formulate the main results of this work. The results are formulated for acceptable groups. It is possible of course to formulate some sharper results and this will be done in §4.

The first result (which should probably be called a lemma rather than a theorem) is

**Theorem A.** Assume that $G$ is acceptable. Let $P$ be a principal $G$-bundle over $A^n$. Then there is an open subscheme $U \subset A^n$ such that $P \times_{A^n} U$ is obtained from a $G$-bundle over $k$ by the base change $U \to \text{Spec} \ k$.

**Theorem B.** Assume that $G$ is connected, smooth, reductive and split. Assume further that the natural map $H^1(k, G) \to H^1(k, \text{Ad}G)$ is trivial (i.e. for every principal homogeneous space over $G$ the principal homogeneous space over the adjoint group $\text{Ad}G$ obtained by extension of structure group is trivial). Then a $G$-bundle $P$ over $A^n$ is trivial if and only if for a non-empty open subscheme $U \subset A^n$, $P \times_{A^n} U$ is obtained from a bundle on $\text{Spec} \ k$ by the base change $U \to \text{Spec} \ k$.

An immediate corollary is

**Theorem C.** Assume that $G$ is connected, acceptable and reductive and that $k$ is ‘separably closed’. Then any principal $G$-bundle over $A^n$ is trivial.
We state one final result which is applicable especially to the case of local fields.

**Theorem D.** Assume that \( G \) is acceptable, connected, semisimple, simply connected and quasi-split. Assume further that the map \( H^1(k, G) \to H^1(k, \text{Ad}G) \) is trivial. Then any principal \( G \)-bundle on \( \mathbb{A}^n \) is trivial.

The following result for the special case \( G = \text{O}(n) \)-which has attracted considerable interest-is proved in §4.

**Theorem E.** Assume that \( \text{Char} k \neq 2 \) and the Brauer group \( \text{Br}(k) \) of \( k \) has no 2-torsion. Then any orthogonal bundle on \( \mathbb{A}^n \) is obtained from an orthogonal bundle on \( \text{Spec} \ k \) by the base change \( \mathbb{A}^n \to \text{Spec} \ k \).

The method of proof closely parallels-and needless to say, is suggested by - Quillen’s in the case of \( \text{GL}(n) \). We need an obvious extension of a lemma of Quillen’s (Theorem 2, §2). Rigidity of the trivial bundle over \( \mathbb{P}^1 \) (not surprisingly) serves as a replacement of the Horrocks theorem used in Quillen’s work. (Parimala [9] gives an example to show that the theorem of Horrocks does not generalise to \( 0(n) \)-bundles).

My thanks are due to many colleagues who took considerable interest in this work. Among them I should mention: Hyman Bass whose lectures in Bombay on his theorem triggered off the present work; C. S. Seshadri with whom I had many stimulating discussions; also R. C. Cowsik, Mohan Kumar, M. Nori and S. Parimala who had helpful comments and suggestions to offer.

2 Some known results

We make use of three essentially known results in our proofs of the main theorems (Theorems B and C). In this section we collect these known results together. (Sketch proofs are given where no proper references are to be found). The first of these is:

**Theorem 1.** Let \( \mathbb{P}^1 \) denote the projective line over \( k \) and \( X \) be any \( k \)-scheme of finite type. Let \( E \) be a principal \( G \)-bundle over \( \mathbb{P}^1 \times X \).
Let $\pi : \mathbb{P}^1 \times X \to X$ be the natural projection. Suppose now that $x_0 : \text{Spec} \, L \to X$ is a closed point such that $E \times x_0 \text{Spec} \, L$ is trivial over $\bar{L}$, the algebraic closure of $L$. Then there exists an open subscheme $U$ of $X$ containing $x_0$ and a principal $G$-bundle $E'$ over $U$ such that $E \times \pi^{-1}(U)$ is isomorphic to $E' \times \pi^{-1}(U)$.

When $E$ is a $GL(n)$-bundle this is a special case of Grothendieck [4, Corollaire 4.6.4.]: note that for the projective line $\mathbb{P}^1$, $H^1(\mathbb{P}^1, O_{\mathbb{P}^1}) = 0$ where $O_{\mathbb{P}^1}$ is the structure sheaf. In this case, one may assume that $E'$ is in addition the trivial $GL(n)$-bundle.

For handling the general case we need

**Lemma.** Any smooth $G$ is isomorphic to a closed subgroup scheme of some $GL(n)$ such that $G(L)(n)/G$ contains no complete reduced subscheme of positive dimension.

Assume the lemma for the present. Then we can think of a $G$-bundle as a $GL(n)$-bundle together with a section in the associated fibre space with $GL(n)/G$ as fibre. From what we have remarked earlier the $GL(n)$-bundle may be assumed trivial so that the section is a morphism $\sigma : \mathbb{P}^1 \times X \to GL(n)/G$. Since $GL(n)/G$ contains no complete subscheme of positive dimension $\sigma$ factors through $\mathbb{P}^1 \times X \to X$ which shows that the $G$-bundle $E$ itself is obtained from a bundle on $X$ by base change $P^1 \times X \to X$.

We have to establish the lemma. We may assume that $G$ is a closed ($k$-) subgroup scheme of $GL(m)$ for some $m$. Let $\rho$ be a ($k$-) representation of $GL(m)$ on a vector space $V$ and $0 \neq v \in V(k)$ be such that $G$ is the isotropy group scheme at $\bar{v}$ for the action of $GL(m)$ on the projective space $\mathcal{P}(V)$ associated to $V$. This means the orbit map $GL(m) \to GL(m)$ $\bar{v}$ is an isomorphism of $GL(m)/G$ on the orbit which is a locally closed subscheme of $\mathcal{P}(V)$. (Here $\bar{v}$ is the closed point of $\mathcal{P}(V)$ determined by $v$). This determines a morphism $\chi : G \to G_m$ such that for any $g \in G(L)$, $L$ a $k$-algebra,

$$\rho(g)v = \chi(g) \cdot v.$$  

If $\chi$ is trivial, $G$ is the isotropy at $v$ for the action of $GL(m)$ on $V$ so that $GL(m)/G$ is locally closed in affine space and the assertion follows. We
assume then that \( \chi \) is non-trivial. Consider the immersion

\[
G \overset{(i, \chi^{-1})}{\longrightarrow} GL(m) \times GL(1) = H.
\]

Let \( I \) denote the identity representation of \( GL(1) \) and \( \rho \otimes I \) the representation of \( H \) obtained by forming the tensor product of \( \rho \) and \( I \). Then the isotropy group at \( v \otimes 1 \) is seen to be precisely \( G \) so that \( (GL(m) \times GL(1))/\gamma G \) is a locally closed subscheme of an affine space. On the other hand, \( GL(m) \times GL(1) \) is in a natural fashion a closed subscheme of \( GL(m+1) \) with affine quotient. It follows that \( GL(m+1)/G \) is a fibre space over an affine scheme with fibres \( (GL(m) \times GL(1))/\gamma G \). The lemma follows immediately from this.

**Theorem 2** (Quillen [10]). Let \( E \) be a \( G \)-bundle on \( \text{Spec} R[T] \approx A^1 \times \text{Spec} R \), \( R \) a \( k \)-algebra. Suppose for every maximal ideal \( \mathfrak{m} \subset R \), \( E \times \text{Spec} R_\mathfrak{m} \) (\( R_\mathfrak{m} = \text{localisation at} \mathfrak{m} \)) is trivial, then \( E \approx F \times \text{Spec} R[T] \) for some \( G \)-bundle \( F \) over \( \text{Spec} R \).

Quillen states and proves this for \( G = GL(n) \). The general case follows by simply changing \( GL(n) \) to \( G \) in his argument.

The next result we need is well known.

**Theorem 3.** Let \( G \) be a ‘split’ connected semisimple group over \( k \). Let \( n = \dim G \) and \( I = \text{rank} G \) (\( = \text{dimension of maximal} k \)-split torus of \( G \)). Then \( G \) contains an affine open subscheme isomorphic to \( A^{n-1} \times \text{Spec} k[T_1, T_1^{-1}, T_2, T_2^{-1}, \ldots, T_1, T_1^{-1}] \).

This is immediate from structure theory: Let \( T \) be a maximal \( k \)-split torus and \( U^\pm \) opposing unipotent maximal \( k \)-subgroup schemes. Then the morphism \( U^+ \times T \times U^- \to G \) given by the multiplication in \( G \) is an isomorphism onto the image \( \Omega \).

**Theorem 4** below must also be regarded as well known: it is a more or less immediate consequence of the work of Chevalley [3] and Steinberg [13]. We give some details, as a proof does not seem to be available explicitly in literature.
Theorem 4. Let $G$ be a simply connected quasi-split (smooth) group scheme. Then $G$ contains an open ($k$-) subscheme $\Omega_0$ such that the inclusion $i : \Omega_0 \to G$ factors through an affine space, i.e. there is a commutative diagram of the form

\[
\begin{array}{ccc}
\Omega_0 & \xrightarrow{i} & G \\
\downarrow & & \downarrow \\
A^r & & \\
\end{array}
\]

(for some integer $r$).

Let $T$ be the centraliser of a $k$-split torus $S$ in $G$. Let $U$ and $U^-$ be opposing maximal unipotent $k$-subgroup schemes of $G$ normalised by $S$. Let $N(S)$ be the normaliser of $S$ in $G$ and $\theta \in N(S)(k)$ an element which conjugates $U$ onto $U^-$. Then the morphism

$U \times T \times U \to G$

defined by $(u, t, u') \mapsto u\theta tu'$ on the set of closed points is an open immersion. As a $k$-scheme $U$ is isomorphic to an affine space $A^q$, $q = \dim U$. It suffices to show that the inclusion $T' \hookrightarrow G$ for some $k$-open subset $T'$ of $T$ factors through an affine space. If $\Delta$ is the system of simple $k$-roots determined by $U$, for each $\alpha \in \Delta$, we have a $k$-rank 1 quasi split subgroup $G_\alpha$ of $G$ such that $T = \prod_{\alpha \in \Delta} T_\alpha$, a direct product with $T_\alpha \subset G_\alpha$. This shows that the problem immediately reduces to the case when $k$-rank $G = 1$. The quasi-split groups of $k$-rank 1 are of one of the following two kinds:

(i) $R_{L/k} SL(2)$,

(ii) $R_{L/K} SU(2, 1)$, $SU(2, 1)$ being the special unitary group of a hermitian form of Witt index 1 over a quadratic extension of $L$ where $L$ is a finite separable extension of $k$. Now for the affine $n$-space $A^n_L$, $R_{L/k} A^n_L$ is isomorphic to $A^{nq}_k$ where $q = \dim_k L$ so that we see that we need only consider the cases of $SL(2)$ and $SU(2, 1)$ over $k$. 
In case $G = SL(2)$, take $T' = T$ and the factorisation sought after results from the product decomposition

$$
\begin{pmatrix}
  t & 0 \\
  0 & t^{-1}
\end{pmatrix} = \begin{pmatrix}
  1 & t \\
  0 & 1
\end{pmatrix} \begin{pmatrix}
  1 & 0 \\
  -t^{-1} & 1
\end{pmatrix} \begin{pmatrix}
  1 & t \\
  0 & 1
\end{pmatrix} \begin{pmatrix}
  0 & -1 \\
  1 & 0
\end{pmatrix}.
$$

Consider now the case $G = SU(2, 1)$: $G$ is the special unitary group of the hermitian quadratic form

$$
\begin{pmatrix}
  0 & 1 & 0 \\
  1 & 0 & 0 \\
  0 & 0 & 1
\end{pmatrix}
$$

in 3 variables over a quadratic Galois extension $K$ over $k$. If we denote by $x \mapsto \bar{x}$ the conjugation by the non-trivial element of the Galois group of $K/k$ as well as its extension to $\tilde{L} = L \otimes_k K$ for any $L \supset K$, the $L$-rational points of a split torus are given by

$$
\varphi(x) = \begin{pmatrix}
  x & 0 & 0 \\
  0 & x^{-1} & 0 \\
  0 & 0 & x^{-1} \bar{x}
\end{pmatrix}, \quad x \in \tilde{L} \text{ invertible.}
$$

We will deal with the cases $\text{Char } k \neq 2$ and $\text{char } k = 2$ separately.

**Case 1.** $\text{Char } k \neq 2$. Let $T'$ be the open set whose $L$-rational points are

$$\
\{\varphi(x)|x - \bar{x} \text{ is invertible in } \tilde{L}\}.
$$

Fix an element $\theta \in K - k$ such that $\theta^2 \in k$. Then any element of $K$ is of the form

$$a + b\theta, a, b \in k,$$

and for any $L \supset k$, $\tilde{L} = L + L\theta$; also for $a + b\theta \in \tilde{L} \supset a, b \in L$, $(a + b\theta)^{-1} = a - b\theta$ so that $\varphi(a + b\theta) \in T'(L)$ if and only if $b$ is invertible in $L$.

Now for $a + b\theta \in \tilde{L}$.

$$\begin{pmatrix}
  a + b\theta & 0 & 0 \\
  0 & (a - b\theta)^{-1} & 0 \\
  0 & 0 & (a + b\theta)^{-1}(a - b\theta)
\end{pmatrix}$$
Case 2. This is the reason why the argument works.

We will now give factorisations of $\lambda(a, b)$ and $\mu(a, b)$ as products $\mu(a, b) = \chi'(a, b)\xi'(a, b)\beta'(a, b)$, $\lambda(a, b) = \alpha(a, b)\xi(a, b)\beta(a, b)$ where $\alpha$, $\alpha'$ and $\beta$, $\beta'$ morphisms of $T'$ in $U$ and $\xi, \xi'$ are morphism of $T$ in $U^{-}$. For $\mu$ this is similar to what we did in the case of $SL(2)$:

$$
\mu(a, b) = \begin{pmatrix}
1 & 2^{-1}b\theta^{-1} & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
1 & 0 & 0 \\
-2b^{-1}\theta & 0 & 0 \\
0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
1 & 2^{-1}b\theta^{-1} & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{pmatrix}
$$

As for $\lambda(a, b)$ this is a trifle more complicated. We write down $\alpha(a, b)$; the others are uniquely determined by $\alpha(a, b)$:

$$
\alpha(a, b) = \begin{pmatrix}
1 & -b^2/2 - ab\theta^{-1}/2 & b \\
0 & 1 & 0 \\
0 & -b & 1
\end{pmatrix}
$$

(Given an element $x \in U(k)$, there are unique elements $y \in U^{-1}(k)$ and $x' \in U(k)$ such that

$$
xyx' \in \text{Normaliser of } S.
$$

This is the reason why the argument works.)

**Case 2.** Char $k = 2$. We pick an element $\theta \in K$ with $\theta + \bar{\theta} = 1$. Then any element of $L$ is of the form $a + b\theta$ with $a, b \in L$. We can then write

$$
\begin{pmatrix}
0 & 0 \\
0 & (a + b\theta)^{-1} \\
0 & 0
\end{pmatrix}
\begin{pmatrix}
a + b\theta \\
0 \\
0
\end{pmatrix}
= \begin{pmatrix}
0 & b^2\theta + ab \\
(b^2\theta + ab)^{-1} & 0 \\
0 & 0
\end{pmatrix}
\begin{pmatrix}
0 & b & 0 \\
0 & 0 & 0 \\
(a, b) & 0 & 1
\end{pmatrix}
$$
= \lambda(a, b) \mu(a, b) \text{ as before.}

Clearly \( \mu(a, b) = \begin{pmatrix} 1 & b & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ -b^{-1} & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \); \ and
\mu(a, b) = \alpha(a, b) \cdot \xi(a, b) \cdot \beta(a, b) \text{ with } \alpha, \beta \in U \text{ and } \xi \in U^-.

As before we write down \( \alpha(a, b) \) explicitly:
\[
\alpha(a, b) = \begin{pmatrix} 1 & b^2 \theta + ab & b \\ 0 & 1 & 0 \\ 0 & b & 1 \end{pmatrix}
\]
(\( \beta \) and \( \xi \) are determined by \( \alpha \)). This completes the proof of Theorem 3.

3 Proofs of the main results (A, B, C, and D).

Throughout this section \( G \) will denote an acceptable (smooth) group scheme over \( k \).

We prove Theorem A first. We argue by induction on \( n \). When \( n = 1 \), this is immediate from the definition of acceptability. Assume that the result holds for \( n \leq m \) and let \( P \) be a \( G \)-bundle on \( A^{m+1} = A \times A^m \).

Let \( \text{Spec } K \rightarrow A^m \) be the generic point of \( A^m \) and \( P^* = P \times_{A^m} \text{Spec } K : P^* \) is a bundle over \( A \times \text{Spec } K \). By the definition of acceptability, there is a \( G \times K \) bundle \( P' \) on \( \text{Spec } K \) such that \( P' \times_{\text{Spec } K} (A^1 \otimes_{k} \text{Spec } K) \approx P^* \).

Equivalently there is an open subscheme \( U \subset A^m \) and a bundle \( P'' \) on \( U \) such that
\[
P \times_{A^m} U \approx P'' \times_{U} (A^1 \times_{k} U).
\]

Let \( p : \text{Spec } k \rightarrow A \) be any \( k \)-point and \( \hat{p} : A^m \rightarrow A \times A^m \) the corresponding immersion. Let
\[
P_1 = P \times_{A \times A^m} (\text{via } \hat{p}).
\]

If we let \( \hat{p} \) also denote the immersion
\[
U \rightarrow A \times_{k} U,
\]
clearly
\[ P_1 \times_{A^m} U \cong P''. \]

By induction hypothesis \( P_1 \) is obtained by base change \( A^m \to \text{Spec } k \) from a principal homogeneous space over \( k \). Thus the same is true of \( P'' \) (with respect to the base change \( U \to \text{Spec } k \)). Since \( P \times_{A^m} U \cong P'' \times_U (A' \times U) \) the desired result follows. This concludes the proof of Theorem A.

We proceed to the proofs of Theorems B and C. For the sake of brief formulations we adopt the following definition: A \( G \)-bundle \( P \) on a \( k \)-scheme \( X \) is obtained from \( k \) if \( P \) is isomorphic to a bundle of the form \( P' \times_X \text{Spec } k \) with \( P' \) a principal homogeneous space over \( k \).

Under the hypotheses in Theorems B and D we can find \( f \in k[X_1, \ldots, X_n](A^n = \text{Spec } k[X_1, \ldots, X_n]) \) such that \( P \) restricted to the open subschemes
\[ W' = \{ p \in A^n | f(p) \neq 0 \} \]
is obtained from \( \text{Spec } k \). After a change of coordinates if necessary one can assume that \( f \) has the form
\[ X_1^m + \sum_{i=0}^{m-1} q_i(X')X'_i \]
with \( q_i(X') \in k[X'] \overset{\text{def}}{=} k[X_2, \ldots, X_n] \). Isolating the variable \( X_1 \) gives a 197 product decomposition
\[ A^n = A^1 \times A^{n-1}. \]

We want to prove the following.

**Assertion 1.** The hypotheses are those of Theorem B or of Theorem D. Then for each closed point \( x_0 \in A^{n-1} \), there is an open neighbourhood \( U_{x_0} \) of \( x_0 \) such that \( P \) restricted to \( A^1 \times U_{x_0} \) is obtained from a bundle \( P_{x_0} \) on \( U_{x_0} \) by the base change \( A^1 \times U_{x_0} \to U_{x_0} \).
Observe that the assertion implies Theorems B and D. To see this we argue as follows. Let \( p : \text{Spec} \, k \to A^1 \) be a \( k \)-point and \( \hat{p} \) the corresponding immersion
\[
A^{n-1} \hookrightarrow A^1 \times A^{n-1}.
\]
Then the restriction of \( P \) to \( A^{n-1} \) is, by an induction assumption, obtained from \( \text{Spec} \, k \). Using a Galois twist of \( P \) we can assume that this bundle is actually trivial. It is then easily seen that the \( P_x \) in the Assertion is necessarily trivial. We can now appeal to Theorem 2 to obtain Theorems B and D.

To prove Assertion 1 we use Theorem 1. Consider the scheme \( \mathcal{P}^1 \times A^{n-1} \). This contains \( A^1 \times A^{n-1} \) as an open \( k \)-subscheme which we note also by \( U_1 \) in the sequel. Let
\[
U'_2 = \mathcal{P}^1 \times A^{n-1} - \{ p \in A^n | f(p) = 0 \}.
\]
Then \( U'_2 \) is an open \( k \)-subscheme as well. Since \( f \) is monic in \( X_1 \), \( U_1 \) and \( U'_2 \) cover \( \mathcal{P}^1 \times A^{n-1} \). Moreover if \( U_1 \cap U'_2 = W' \) and \( P \) restricted to \( W' \) is obtained from \( \text{Spec} \, k \). We may, after a twist assume then that \( P \) restricted to \( W' \) is actually trivial. Since \( H^1(k, G) \to H^1(k, AdG) \) is trivial, this does not change \( G \). Fix once and for all an isomorphism
\[
P \bigg|_{U_1 \cap U'_2} \sim 1_{G,W'}
\]
where \( 1_{G,W'} \) is the trivial bundle on \( W' \). Now let \( x_0 : \text{Spec} \, L \to A^{n-1} \) be any closed point and \( \tilde{x}_0 \) the induced morphism
\[
\mathcal{P}^1 \times \text{Spec} \, L \to \mathcal{P}^1 \times A^{n-1}.
\]
For an open subscheme \( V \) of \( \mathcal{P}^1 \times A^{n-1} \) we denote by \( V_{x_0} \) the inverse image of \( V \) in \( \mathcal{P}^1 \times \text{Spec} \, L \). In particular then \( U_{1x_0} \) and \( U'_{2x_0} \) cover \( \mathcal{P}^1 \times \text{Spec} \, L \). Let \( P_{x_0} \) denote the bundle on \( A^1 \times \text{Spec} \, L \) induced by \( P \). Since \( G \) is acceptable \( P_{x_0} \) is obtained from \( L \) and, since \( P \) is trivial on \( W' \) and \( W'_{x_0} \) is non-empty (note that \( f \) is monic in \( X_1 \)) \( P_{x_0} \) is trivial. Let
\[
\theta : P_{x_0} \simeq G \times (A^1 \times \text{Spec} \, L)
\]
be an isomorphism. On the other hand, \( \Phi_0 \) by restriction gives an isomorphism
\[
\varphi_0 : P_{x_0}|_{W_{x_0}} \cong G \times W'_{x_0}.
\]
Let \( \alpha = \theta_0 \varphi_0^{-1} \) be the composite isomorphism
\[
\alpha : G \times W'_{x_0} \to G \times W'_{x_0}.
\]
\( \alpha \) gives rise to and is determined by a morphism
\[
\Psi_1 : W'_{x_0} \to G.
\]
We will deduce Assertion 1 from

**Assertion 2.** Let \( x_0 \in A^{n-1} \) be any closed point. Then there is a refinement \((U_1, U_2)\) of \((U_1, U'_2)\) with the following properties:

(i) there is a neighbourhood \( V \) of \( x_0 \in A^{n-1} \) such that
\[
U_1 \cup U_2 \supseteq \mathcal{P}^1_{\text{Spec} k} \times V,
\]
(ii) if \( W = U_1 \cap U_2, \psi = \psi_1|_{W_{x_0}} \) extends to a morphism \( \overline{\Psi} \) of \( W \) in \( G \).

If we admit Assertion 2, we can construct a bundle \( \tilde{P} \) on \( \mathcal{P}^1_{\text{Spec} k} \times V \) as follows: Let \( 1_{G, U_2} \) be the trivial \( G \)-bundle on \( U_2 \). Then \( \Psi \circ \Phi_0 \) gives an isomorphism of \( P \) restricted to \( W \) with \( 1_{G, U_2} \) restricted to \( W \). Patching by this isomorphism we obtain a bundle on \( U_1 \cup U_2 \) whose restriction to \( \mathcal{P}^1 \times V \) we denote \( \tilde{P} \). From the fact that \( \overline{\Psi} \) extends \( \psi \), it is immediate that the bundle on \( \mathcal{P}^1 \times \text{Spec} L \) obtained by the base-change \( x_0 : \text{Spec} L \to V \) is trivial. By Theorem 1, \( \tilde{P} \) is locally obtained by base change from a \( G \)-bundle on a neighbourhood of \( x_0 \). Since \( \tilde{P} \) has \( P \) for its restriction to \( A^1 \times V \), Assertion 1 follows.

We are still to establish Assertion 2. We consider the hypotheses of the two theorems separately.

**Case i** (Hypotheses as in Theorem B). Choose \( \Omega \) as in the proof of Theorem 3 of \( \S 2 \) \( \Omega \cong \text{Spec} k[X_1, \ldots, X_q, T_1 \ldots T_1 T_1^{-1} \ldots T_1^{-1}] \) (1 = k-rank
\( G, q^+ = \dim G \). Let \( S = \psi_1^{-1}(G - \Omega) \). This is a \( k \)-closed subset of \( W'_{x_0} \) since \( \dim W'_{x_0} = 1 \), if \( S \) is a proper subset, \( S \) in finite hence closed in \( U_{1, x_0} (\simeq \text{Spec } L[X_1]) \); and we assume that \( S \neq W'_{x_0} \) by replacing \( \Omega \) if necessary by a translate by an element of \( G(k) \). (This is evident when \( G(k) \) is dense in \( G \) but one can give an obvious argument using the Bruhat-decomposition even if \( G(k) \) were not dense in \( G \)). The affine scheme \( W'_{x_0} \) is of the form \( \text{Spec } L \left[ X_1, \frac{1}{f^*} \right] \) where \( f^* \in L[X_1] \) is the polynomial \( X_1^m + \sum_{i=0}^{m-1} q_i(x_0)X_1^i \). The morphism \( \Psi_1 \) gives a ring homomorphism

\[ \psi_1^* : k[X_j, T_i, T_i^{-1}(1 \leq j \leq q, 1 \leq i \leq 1)] \to L(X_1). \]

Let \( \psi_1^*(X_j) = (Q_j/R_j) \) and \( \psi_1^*(T_i) = A_i/B_i \) where \( (Q_j, R_j) \) and \( (A_i, B_i) \) are coprime polynomials in \( L[X_1] \). Let degree \( R_j = r_j \), degree \( A_i = a_i \) and degree \( B_i = b_i \). Choose elements \( (\tilde{A}_i, \tilde{B}_i, \tilde{Q}_j) \) and \( \tilde{R}_j \) in \( k[X_1, \ldots, X_n] \) such that

(i) \( \tilde{A}_i \) (resp. \( \tilde{B}_i, \tilde{Q}_j, \tilde{R}_j \)) is a lift of \( A_i \) (resp. \( B_i, Q_j, R_j \)) for the map \( \tilde{x}_0 : k[X_1, \ldots, X_n] \to L[X_1] \),

(ii) degree \( \tilde{A}_i \) (resp. \( \tilde{B}_i, \tilde{R}_j \)) in \( X_1 \) is precisely \( a_i \) (resp. \( b_i, r_j \)).

Let \( \alpha_i \) (resp. \( \beta_i, \rho_j \)) denote the leading coefficients of \( \tilde{A}_i \) (resp. \( \tilde{B}_i, \tilde{R}_j \)) as a polynomial in \( X_1 : \alpha_i, \beta_i, \rho_j \) belong to \( k[X_2, \ldots, X_n] \). These elements do not take the value zero at \( x_0 \). Let \( V \) be the open neighbourhood of \( x_0 \) defined by

\[ V = \{ p \in A^{n-1} | \alpha_i(p) \neq 0, \beta_i(p) \neq 0, \rho_j(p) \neq 0, 1 \leq i \leq l, 1 \leq j \leq q \}. \]

Let \( U_2 = U'_2 - \{ p \in A^n | \prod_{1 \leq i \leq l} A_i B_i R_j(p) = 0 \} \). This choice of \( U_2 \) and \( V \) is easily seen to satisfy the conditions of Assertion 2.

**Case ii** (Hypotheses as in Theorem D). Since \( G \) is quasi split and simply connected we can choose (Theorem 4 of §2) an open subset \( \Omega_0 \) such that the inclusion \( \Omega_0 \subset G \) factors through an affine space \( : \Omega_0 \to A^r \to G \).
Let $S = \psi_{-1}^{-1}(G - \Omega_0)$. We may assume that $S$ is finite (if $\Omega_0$ is chosen exactly as in Theorem 4 of §2 this can be secured by translating $\Omega_0$ by an element of $G(k)$). Let $f_0 \in k[X_1]$ be a monic polynomial vanishing on $S \subset \text{Spec } L[X_1])$. Consider $f_0$ as an element of $k[X_1, \ldots, X_n]$ and let $U_2 = U'_2 - \{p \in A^n | f_0(p) = 0\}$. Since $f_0$ is monic in $X_1$, $U_1 \cup U_2 = \mathbb{P}^1 \times A^{n-1}$ with this choice of $U_2$, $\psi$ factors through $\Omega_0 : \psi_1(W_{x_0}) \subset \Omega_0$. Since $\Omega_0 \hookrightarrow G$ factors through $A^r$, $\psi$ extends (from the closed set $W_{x_0}$) to all of $W : \psi : W \to G$. This proves Assertion 2 in this case.

4 Complements

We discuss first some special fields.

1. Fields of Dimension $\leq 1$. If $k$ is a field of dimension 1, $H^1(k, G) = 0$ for all smooth connected $G$ (Lang [7], Steinberg [14]). Thus Theorem B is applicable to any acceptable semisimple $G$ over $k$. We conclude that for such $k$ any $G$-bundle on $A^n$ is trivial. Among the fields covered are:

   (i) finite fields;

   (ii) $k = L(X)$, the pure transcendental extension of degree 1 over an algebraically closed field $L$;

   (iii) $k$ is the maximal unramified extension of a local field.

2. Local fields with residue fields of dimension $\leq 1$. For such $k$, it is known (Bruhat-Tits [2]) that $H^1(k, G) = 0$ for any simply connected $G$. Thus Theorem D is applicable: Any $G$-bundle with $G$ quasi-split and simply connected on an affine space is trivial. The fields that are covered are:

   (i) finite extensions of $p$-adic fields,

   (ii) quotient fields of power series rings $k'[[T]]$ in 1 variable with $\text{dim } k' \leq 1$. 
3. **Global fields.** Here again it is known that for a simply connected acceptable $G$, $H^1(k, G) = 0$ except possibly when $G$ has exceptional factors and $k$ is a number field which admits a real place (Harder \[5a], \[5b], Kneser \[6b\]). Thus for any quasi-split $G$, $G$-bundles on $A^n$ are trivial for simply connected classical $G$ over a number field $k$.

The following groups are acceptable for *any* field $k$: $GL(n)$, $Sp(n)$ Spin $f$, $f$ a split quadratic form (in more than 3 variables). This is obvious for $GL(n)$ and $Sp(n)$ and can be deduced from Harder’s theorem for $SO(n)$ in the case of Spin groups. Theorem \[D\] is applicable in all these cases because in addition, $H^1(k, G) = 0$ for all these groups.-Note that for Spin we have taken the split form (see Serre \[12\], III-25).

We have therefore

**Theorem D’.** Let $G$ be a split simply connected ‘classical’ group over any field $k$. Then any $G$-bundle over $A^n$ is trivial.

Next observe that Theorem \[C\] gives the following

**Proposition.** If $G$ is an acceptable $k$-group, there is a bijective correspondence between isomorphism of classes of principal $G$-bundles on $A^n$ and the Galois cohomology set

$$H^1(\pi, G(\bar{k}_s[X_1, \ldots, X_n]))$$

where $\bar{k}_s$ = separable closure of $k$ and $\pi$ is the Galois group of $\bar{k}_s$ over $k$.

As a corollary we will prove

**Theorem E.** Let $k$ be such that $Br(k)$ has no 2-torsion and $Char k \neq 2$. Then any orthogonal bundle over $A^n$ is obtained by base change from $k$.

**Theorem E’.** Let $k$ be a field such that $Br(k)$ has no 2-torsion and $Char k \neq 2$. Then every non-singular quadratic form over $k[X_1, \ldots, X_n]$ is equivalent to one over $k$. 
For the proof we need

**Lemma.** Let $k$ be a field such that $Br(k)$ has no 2-torsion. Then

(i) a quadratic form over $k$ is determined by the discriminant;

(ii) if the number of variables is $n \geq 3$, the Witt-index is at least $\lfloor (n-1)/2 \rfloor$ (integral part of $(n-1)/2$).

(iii) the spinor norm is surjective for any form $f$;

(iv) for any quadratic form $f$, $SO(f)$ is quasi-split over $k$ (if the number of variables is at least 3);

(v) for any form $f$, $H^1(k, \text{Spin } f) = 0$.

**Proof.** To prove (i) we argue by induction on the number of variables, we may assume that the quadratic form is the orthogonal sum

$$q \perp \lambda$$

where $q$ is a form in $(n-1)$ variables $\lambda \in k$ and $\lambda$ is the form in 1 variable $x \mapsto \lambda x^2$, $x \in k$. By induction hypothesis $q$ is isomorphic to the orthogonal sum

$$1 \perp d$$

where $1$ is the identity form in $(n-2)$ variables, $d \in k$ and $d$ is the form $x \mapsto dx^2$ on $k$. It suffices then to show that $d \perp \lambda$ is isomorphic to $1 \perp \lambda d$ (with the obvious notation). In order to prove this, we have to show that any quadratic form in 2 variables represents 1. In fact, we prove the following stronger statement which immediately implies (iii) as well:

Let $\alpha \neq 0$ be any element of $k$; then the quadratic form $\lambda \perp \mu$ for any pair $\lambda, \mu \in k^*$ represents $\alpha$.

We have to solve the equation

$$\lambda x^2 + \mu y^2 = \alpha$$

or equivalently
This is the same as proving that $\alpha/\lambda$ is a norm for the quadratic extension $k(\sqrt{-\mu/\lambda})$. Since there are no quaternion division algebras over $k$, this is indeed true (see for instance, O’Meara [15], p. 146).

We have thus proved (i) and (ii). Statement (iii) is immediate from (i): if $q$ is any quadratic form in $m = 2n + 2$ (resp. $2n + 1$) variables and $h$ is the hyperbolic form in $2n$ variables, $q \simeq h \perp 1 \perp d$ (resp. $h \perp d$) where $d' \in k$ is any representative for the discriminant and $d = \pm d'$.

To prove (iv) again write

\[
q \simeq h \perp d \quad \text{or} \quad q \simeq h \perp 1 \perp d
\]

according as the number of variables is odd or even. Let $E$ be the maximal isotropic subspace for $h$. Then the subgroup $P$ of $SO(q)$ which fixes $E$ is a parabolic subgroup. Writing $q$ as

\[
q \simeq h \perp q'
\]

(where $\dim q' \leq 2$) we see that the reductive part $M$ of $P$ is isomorphic locally to the product of a torus and $SO(q')$. It follows that (since $\dim q' \leq 2$) $M$ is a torus. Thus $P$ is a Borel subgroup. This proves (iv).

Finally (v) follows from (i) and (iii) in view of the following known fact (Serre [12, III-25]).

If $f$ is a quadratic form such that the Spinor norm map is surjective and every form $f'$ with the same Witt-index and discriminant as $f$ (in the same number of variables) is equivalent to $f$, then $H^1(k, \text{Spin } f) = 0$. This proves (v).

We proceed to the proof of Theorem [E] now. When the number of variables is 2 this is trivial. We assume therefore that the number of variables is at least 3. Observe first that for any quadratic form $f$ over $k$,

\[
H^1(\pi, \text{Spin } f(k_s[X])) = 0
\]
where \( k_s = \) separable closure of \( k \) and \( \pi = \text{Gal}(k_s/k) \). This follows from Theorem C combined with Parts (iv) and (v) of the lemma above. Next consider the exact sequence

\[
1 \to \{\pm 1\} \to \text{Spin } f \to SO(f) \to 1.
\]

Since \( \text{Char } k \neq 2 \), one sees immediately that the sequence

\[ 1 \to \{\pm 1\} \to \text{Spin } f(k_s[X]) \to SO(f)(k_s[X]) \to 1 \]

is exact. The cohomology sequence gives exactness of

\[
\begin{array}{ccc}
H^1(\pi, \text{Spin } f(k_s[X])) & \longrightarrow & H^1(\pi, SO(f)(k_s[X])) \\
\| & & \| \\
0 & & 0
\end{array}
\]

The last group is trivial since \( Br(k) \) has no 2-torsion.

Thus for any \( f \), \( H^1(\pi, SO(f)(k_s[X])) = 0 \). Now consider the split exact sequence for a fixed \( f_0 \)

\[ 1 \to SO(f_0)(k_s[X]) \to 0(f_0)(k_s[X]) \to \{\pm 1\} \to 1. \]

This gives in cohomology the sequence

\[ 0 \to H^1(\pi, 0(f_0)(k_s[X])) \xrightarrow{\eta} H^1(\pi, \{\pm 1\}). \]  \hfill (*)

The fibre over the trivial element is thus trivial. We want to show that the fibre over \textit{any} element of \( H^1(\pi, \{\pm 1\}) \) is trivial. Using the splitting the fibre can be identified (by a standard twisting argument) with the fibre over the trivial element for a twisted form \( f \) of \( f_0 \):

\[ H^1(\pi, O(f)k_s[X]) \to H^1(\pi, \{\pm 1\}); \]

and since \( H^1(\pi, SO(f)(k_s[X])) = 0 \) it follows that \( \eta \) in (*) is a bijection. Comparing with the Galois cohomology for \( k_s \)-points we conclude that \( H^1(\pi, O(f_0)(k_s[X])) \) is in bijective correspondence with \( H^1(\pi, O(f_0)(k_s)) \). To conclude the proof of Theorem E we need only show that \( H^1(\pi, O(f_0) \)
\( k_s[X] \) classifies quadratic forms over \( k[X] \). Equivalently we have to show that all orthogonal bundles over \( \text{Spec} \, k_s[X] \) are trivial. And this follows from Theorem B since (in view of our assumption that \( \text{Char} \, k \neq 2 \)) any \( O(n) \)-bundle admits an \( SO(n) \)-reduction.

205 Remarks. (I). Theorems can be formulated for general connected \( G \) using the main results of this paper. For this one takes into account the following facts:

(i) For a split unipotent \( G \) any principal \( G \)-bundle is trivial (This is obvious).

(ii) If \( T \) is a torus then any torus bundle over \( A^n \) is obtained by base change from \( k \), (This can be proved by the following observations. When \( k \) is separably closed this amounts to saying that all line bundles are trivial; the general case follows from Galois cohomology once one observes that \( T(\bar{k}_s[X]) \sim T(\bar{k}) \)).

(II). Theorem A has the following consequence: Given any \( G \)-bundle \( P, G \) acceptable, over \( A^n \), there is a product decomposition \( A^n \cong A^1 \times A^{n-1} \) such that \( P \) extends to a bundle over \( \mathcal{P}^1 \times A^{n-1} \). This suggests that a classification of \( G \)-bundles over \( A^n \) is closely connected with the study of families of bundles on \( \mathcal{P}^1 \).

(III). One can prove a sharper result than Theorem D for quasi-split groups. The statement is:

Assume that \( G \) is quasi-split acceptable and that the map \( H^1(k, G) \to H^1(k, \text{AdG}) \) is trivial. Suppose further that the central isogeny \( \tilde{G} \to G \) of the simply connected covering group \( \tilde{G} \) on \( G \) is separable. Then any principal \( G \)-bundle on \( A^n \) is obtained by base change from \( k \).

This is proved by looking at the Galois cohomology exact sequence (for \( k_s[X] \) rational points) associated to the exact sequence

\[
1 \to C \to \tilde{G} \to G \to 1
\]
It appears likely that the hypothesis that the isogeny is separable is not really necessary.

Geometry of $G/P$-I
Theory of Standard Monomials for Minuscule Representations

By C.S. Seshadri

**Introduction.** Let $G$ be a semi-simple simply connected algebraic group defined over an algebraically closed field $k$. Let $P$ be a maximal parabolic subgroup in $G$ and $L$ the ample line bundle on $G/P$ which generates $\operatorname{Pic} G/P$. We say that $P$ is **minuscule** if the Weyl group $W$ (fixing of course a Borel subgroup, maximal torus etc.) acts transitively on the weight vectors of the irreducible $G$-module $H^0(G/P, L)$ ($k$ assumed to be of characteristic zero. Note then that $H^0(G/P, L)$ is the irreducible $G$-module associated to a fundamental weight). We can then index these weight vectors by $\{p_\tau\}$, $\tau \in W/W_i(P)$ (where $W_i(P)$ denotes the Weyl group of the maximal parabolic subgroup $i(P)$ which is the transform of $P$ under the Weyl involution $i$) so that $p_\tau$ is the highest weight vector, when $\tau \equiv \text{Identity} \pmod{W_i(P)}$. We say that a monomial in $\{p_\tau\}$, say

$$p_{\tau_1} p_{\tau_2} \cdots p_{\tau_m} \in H^0(G/P, L^m)$$

is **standard** if $\tau_1 \leq \tau_2 \leq \ldots \leq \tau_m$ (cf. Def. 1). Then the main result of this paper is the following (cf. Th. 1):

*Standard monomials of length $m$, which are distinct, form a basis of $H^0(G/P, L^m)$, $m \geq 0$, $P$ minuscule.*

(*)

It is proved that this result holds also in arbitrary characteristic.

When $G = SL(n)$, every maximal parabolic subgroup is minuscule. In this case, when the base field $k$ is of characteristic zero, (*) is due
to Hodge (cf. [9], [10]) and is related to Young tableaux. When \( k \) is of arbitrary characteristic, again for \( G = SL(n) \), (*) was proved to be true by many, for example, by Musili (cf. [13]). That the generalisation is to be sought for a minuscule \( P \), was pointed out to the author by A. Borel.

An important consequence of (*) is that it allows one to determine the ideal defining a Schubert variety in \( G/P \), the scheme theoretic unions and intersections of Schubert varieties and the scheme theoretic hyperplane intersection of a Schubert variety, when this intersection decomposes into a union of Schubert varieties (cf. Th. 1). One knows (cf. [12]) that these are the main technical difficulties in trying to prove the following:

\[
H^i(G/B, L) = 0, \quad i > 0, \quad L \text{ in the dominant chamber.} \quad (**)
\]

The essential achievement of G. Kempf, in his proof of (**) (cf. [11]), is that he is able to manage these technical difficulties for \( G \) of type \( E_6, E_7, E_8 \) and \( F_4 \) and \( P \) associated to what he calls a *distinguished weight*. For the cases \( E_6 \) and \( E_7 \), there exists a distinguished weight which is also minuscule. Hence from (*), a proof of (**) for \( G \) of type \( E_6 \) and \( E_7 \) follows on the lines as in [12].

In another place, we shall given an application of (*) to the work of C. De Concini and C. Procesi (cf. [7]) on their generalisation (to arbitrary characteristic) of the classical theorems on invariants, which are found, for example, in H. Weyl (cf. [24]).

The proof of Theorem 1 is related to the one in [13]. The two new simple observations which have made the present generalisation possible and which the author missed for a long time, are as follows:

(i) it suffices to do the standard monomial theory when the base field is of characteristic zero (cf. Remark 5);

(ii) it is not necessary to have, *a priori*, the quadratic relations defining \( G/P \) in its canonical projective imbedding, in the specific form used in [13]. Such quadratic relations follow, once one has the theorem on standard monomials (cf. Corollary 1, Theorem 1).

The proof of Theorem 1 is somewhat indirect and uses Demazure’s results (cf. [8]) that Schubert varieties are Cohen-Macaulay when the
ground field is of characteristic zero. One can give a more direct proof, closer to that of [13], if the following could be checked directly when the ground field is of characteristic zero (cf. Remark 8).

\[ \dim H^0(G/P, L^2) = \# \text{(Distinct standard monomials of degree 2)}. \]

This could perhaps be done by a clever handling of the Weyl’s or De-mazure’s character or dimension formula.

Chapter 1

Standard Monomials

1 Notations and preliminaries (cf. [1], [2], [3], [5], [12]).

\( G = \) a semi-simple, simply-connected, split (Chevalley) group over a field \( k \). Note that \( G \) has also a \( \mathbb{Z} \)-form i.e., \( G \) can be considered as \( G' \otimes_{\mathbb{Z}} k \), where \( G \) is split, semi-simple over \( \mathbb{Z} \) etc.

\( T = \) a maximal torus of \( G; B = \) a Borel subgroup of \( G, B \supset T \). Roots and weights indicated below are taken in the usual sense having fixed \( T \) and \( B \).

\( \Delta = \) system of roots, \( \Delta^+ = \) system of positive roots
\( S = \) simple roots: \( \alpha_i, 1 \leq i \leq l \), or the set \([1, \ldots, l]\)
\( W = \) Weyl group with simple reflections \( s_i(= s_{\alpha_i}), 1 \leq i \leq l \)
\( \check{\omega}_i = \) fundamental weights, \( 1 \leq i \leq l \), i.e., \( \langle \check{\omega}_i, \check{\alpha}_j \rangle = \delta_{ij} \) where \( \check{\alpha}_j \)
denotes the coroot of \( \alpha_j \) and \( \langle, \rangle \) is as in [4].
\( \mathcal{U}_\infty = \) unipotent group \( \approx G_a \) associated to \( \alpha \in \Delta \).
\( \omega_0 = \) the element of maximal length in \( W \)
\( i = \) the Weyl involution - \( \omega_0 \).

Let \( P \) be a parabolic subgroup of \( G, P \supset B \). Then \( P \) is determined by a subset \( S_P \) of \( S \) i.e. \( P \) is generated by \( B \) and \( \mathcal{U}_{-\alpha}, \alpha = \sum n_i \alpha_i, n_i \geq 0, \alpha_i \in S_P \). Set

\[ \Delta_P = \{ \alpha \in \Delta/\alpha = \sum n_i \alpha_i, \alpha_i \in S_P, n_i \in \mathbb{Z} \} \]
\[ \Delta^+_P = \left\{ \alpha \in \Delta / \alpha = \sum n_i \alpha_i, \alpha_i \in S_P, n_i \geq 0, n_i \in \mathbb{Z} \right\} \]

\[ \Delta^-_P = \left\{ \right. \text{with } n_i \leq 0, n_i \in \mathbb{Z} \left. \right\} \]

We have \( P = M_P \cdot U_P \)

\( M_P \) being generated by \( T \) and \( \mathcal{U}_\alpha, \alpha \in \Delta_P \) and \( U_P \) being generated by \( \mathcal{U}_\alpha, \alpha \in \Delta^+, \alpha \notin \Delta^+_P \). One knows that \( U_P \) is the unipotent radical of \( P \) and that \( M_P \) is reductive so that \( M_P \) (resp. \( U_P \)) is called the reductive (resp. unipotent) part of \( P \).

The subgroup \( W_P \) of \( W \) generated by the simple reflections \( s_\alpha, \alpha \in S_P \), is called the Weyl group of \( P \). One sees that \( W_P \) is in fact the Weyl group of the reductive part \( M_P \) of \( P \). The radical of \( M_P \) is a torus, whose dimension = \( \#(S - S_P) \). Hence the character group (i.e. group of homomorphisms into \( \mathbb{G}_m \)) of \( P \) (or of \( M_P \)), considered as an abelian group is free of rank = \( \#(S - S_P) \). One sees that the character group of \( P \) can be identified with the group of characters \( \chi \) of \( T \) such that \( \omega(\chi) = \chi \forall \omega \in W_P \). From this fact it is seen easily that \( \{ \sigma_i \}, i \in S - S_P \) form a basis of the character group of \( P \).

In the sequel we will be working with a maximal parabolic subgroup \( P \). We write \( i_0 = S - S_P \) and \( \sigma = \sigma_{i_0}, i_0 \in [1, \ldots, l] = S \). We assume that the base field \( k \) is algebraically closed.

Let \( V \) denote the space of regular functions \( f \) on \( G \) such that

\[ f(gb) = \chi_{\sigma}(b)f(g) \]

where \( \chi_{\sigma} \) denotes the character of \( B \) defined by the fundamental weight \( \sigma \). Then \( V \) can be identified with the space of sections of the line bundle \( L \) on \( G/B \) associated to the character \( \chi^{-1}_{\sigma} : B \to k \) of \( B \). Now \( \chi_{\sigma} \) extends to a character of \( P \) and \( V \) can in fact be identified with \( H^0(G/P, L) \), where by the same \( L \) we denote the line bundle associated to the character \( \chi^{-1}_{\sigma} : P \to k \). Now \( V \) has a unique \( B \)-fixed line and let us fix a generator \( F \) of this line. We have

\[ F(b_1gb_2) = \chi^{-1}_{i(\sigma)}(b_1)F(g)\chi_{\sigma}(b_2), \ b_i \in B. \]

If \( f : G \to k \) is a regular function on \( G \), we define
We find
\[ b_1 \cdot F(g) = F(b_1^{-1}g) = \chi_i(\varpi)F(g) \]
so that the weight of \( F \) is \( i(\varpi) \) i.e. the highest weight of \( V \) is \( i(\varpi) \).

For \( w \in W \), we denote by \( X(w) \) the Schubert variety associated to \( w \) i.e. the closure \( \overline{BwB} \) of \( BwB \) in \( G \). Let \( X_0 \) denote the set of zeros of \( F \). Then it is \( P \)-stable on the right and \( B \)-stable on the left. We denote by the same \( X_0 \) the subvariety of \( G/P \) defined by \( X_0 \). Then \( X_0 \) is the unique codimension one Schubert variety in \( G/P \). We claim that
\[ X_0 = X(\omega_0 s) = X(i(s)\omega_0), s = s_{i_0}, i_0 = S - S_P, i(s) = \omega_0 s\omega_0. \]

To check this, since \( X(\omega_0 s) \) is of codimension one in \( G/B \), it suffices to check that \( X(\omega_0 s) \) is \( P \)-stable on the right. This is a consequence of Prop. 1.4, [12] and by this proposition we have only to check that
\[ (\omega_0 s)(\alpha) < 0 \quad \forall \alpha \in \Delta_P^+. \]

Hence it suffices to check that
\[ s(\alpha) \in \Delta^+, \alpha = \alpha_i, i \in S_P \text{ i.e. } i \neq i_0, s = s_{i_0}. \]

We have \( s_{i_0}(\alpha_i) \in \Delta^+, i \neq i_0 \) and thus the claim that \( X_0 = X(\omega_0 s) \) is proved.

We observe now that the set \( hX_0 \), \( h \in G \), is precisely the zero set of \( L_h F = F(h^{-1}g) \). We observe that for \( t \in T \), \( t \) leaves stable the set \( X_0 \) and hence the notation \( \tau X_0 \), \( \tau \in W \) makes sense. Now if \( \tau \in W \), \( \tau \cdot F(g) = F(\tau^{-1}g) \) is well-defined only up to a scalar multiple; however we use this notation as it is convenient for us.

Note that the Weyl group \( W \) does not operate even on the projective space \( \mathbb{P}(V) \) associated to \( V \) (as the torus operates with different weights on the weight vectors). Of course the normaliser \( N(T) \) of \( T \) operates on \( V \).
2 Preliminaries on the ideals of Schubert varieties in \( G/P \).

**Lemma 1.** For \( \tau \in W \), we have

\[
\tau X_0 = X_0 \iff \tau \in W_{i(P)}
\]

where \( i(P) \) denotes the maximal parabolic group \( w_0P \omega_0 \) (i.e. the parabolic subgroup associated to the subset \( i(S_P) \) of \( S \)).

**Proof.** Observe that the action of \( W \) on the characters \( \chi \) of \( T \) is defined as follows:

\[
\tau \cdot \chi(t) = \chi(\tau^{-1} t \tau)
\]

We have then \((\tau_1 \tau_2) \cdot \chi = \tau_1 \cdot (\tau_2 \chi)\). Define \( H(g) \) by

\[
H(g) = F(\tau^{-1} g) = L_\tau F(g), \quad g \in G.
\]

The zero set of \( H(g) \) is \( \tau X_0 \) as mentioned above. We have

\[
t \cdot H(g) = H(t^{-1} g) = F(\tau^{-1} t^{-1} g) = F(\tau^{-1} t^{-1} \tau \tau^{-1} g) \\
= \chi_{i(\omega)}((\tau^{-1} t^{-1} \tau)^{-1})F(\tau^{-1} g) = \chi_{i(\omega)}(\tau^{-1} t \tau)H(g) \\
= \chi_{\tau i(\omega)}(t)H(g).
\]

This shows that \( H(g) \) is a weight vector under \( T \) with weight \( \chi_{\tau i(\omega)} \). By the uniqueness of the codimension one Schubert variety in \( G/P \) and the fact that \( F \) is the unique (upto scalars) element in \( V \) with weight \( i(\omega) \), it follows that

\[
\tau X_0 = X_0 \iff X_0 = \text{zero set of } H(g) \\
\iff \tau i(\omega) = i(\omega) \quad \text{i.e } \tau \in W_{i(P)}.
\]

This completes the proof of Lemma 1. \( \square \)

**Lemma 2.** The correspondence

\[
\tau \mapsto X(\tau w_0) = B\tau w_0 P, \quad \tau \in W
\]

induces a bijection of \( W/W_{i(P)} \) onto the set of Schubert varieties in \( G/P \).
Proof. We have the following:

\[ X(\tau_1 \omega_0) = X(\tau_2 \omega_0) \iff \tau_1 \omega_0 = \tau_2 \omega_0 \theta, \theta \in W_P \]
\[ \iff \tau_1 = \tau_2 (\omega_0 \theta w_0) \iff \tau_1 = \tau_2 \lambda, \lambda \in W_i(P). \]

This proves Lemma 2. \(\square\)

**Definition 1.** We write \(\tau_1 \leq \tau_2\) for \(\tau_i \in W/W_i(P)\), whenever \(X(\tau_1 \omega_0) \supseteq X(\tau_2 \omega_0)\). In a similar fashion we write \(\tau_1 \geq \tau_2\), \(\tau_1 \geq \tau_2\) or \(\tau_1 \leq \tau_2\).

We see that \(\tau_1 \leq \tau_2\), \(\tau_i \in W/W_i(P)\), if and only if we can find representatives of \(\tau_i\) in \(W\) (represented by the same letters \(\tau_i\)) such that a reduced expression of \(\tau_2 \omega_0\) (resp. \(\tau_1\)) can be obtained as a “subword” from a reduced expression of \(\tau_1 \omega_0 \theta\) (resp. \(\tau_2 \lambda\)), \(\theta \in W_P\) (resp. \(\lambda \in W_i(P)\)) (cf. p. 98, Prop. 1.7, [12]).

**Lemma 3.** We have the following:

(i) \(X(\tau_1 w_0) \not\subset \tau_2 X_0\) if \(\tau_2 \geq \tau_1\)

(ii) \(X(\tau_2 w_0) \subset \tau_2 X_0\) if \(\tau_2 \not\geq \tau_1\)

eq (i) and (ii) can be written as

\[ X(\tau_1 w_0) \not\subseteq \tau_2 X_0 \iff \tau_2 \not\geq \tau_1. \]

**Proof.** (i) We observe first that

\[ X(\tau_1 w_0) \not\subset \tau_1 X_0. \]

To see this, suppose that this is not the case. Then we have

\[ \tau_1 w_0 \in \tau_1 X_0 \] which implies that \(w_0 \in X_0\).

This leads to a contradiction (for this would mean \(X_0 = \text{big cell}\)).

Suppose that \(\tau_2 \geq \tau_1\). Then \(X(\tau_2 \omega_0) \subset X(\tau_1 \omega_0)\). We have

\[ X(\tau_2 \omega_0) \not\subset \tau_2 X_0 \]

This implies, *a fortiori*, that \(X(\tau_1 w_0) \not\subset \tau_2 X_0\).
(ii) We have to show that
\[ \tau_2^{-1}X(\tau_2w_0) \subset X_0 \text{ if } \tau_2 \neq \tau_1. \]

Let \( C(w) = BwP \) (Bruhat or Schubert cell). It suffices to check that
\[ \tau_2^{-1}C(\tau_1w_0) \subset X_0. \]

Choose a representative of \( \tau_2 \) in \( W \) and a reduced decomposition
\[ \tau_2 = s_1 \ldots s_p \]

By the axioms (or properties) of a Tits system (axiom T-3 and its easy consequence, cf. [4] pp. 22-23), we deduce that
\[ \tau_2^{-1}C(\tau_1w_0) \subset \bigcup_{(s_i \ldots s_k)} B(s_i \ldots s_k)\tau_1w_0P \quad (*) \]

where \((s_i \ldots s_k)\) runs through all “subwords” of \( s_1 \ldots s_p \) (i.e. a word consisting of a subset of \( s_1, \ldots, s_p \) and written in the same order). Note that \( s_i \ldots s_i = (s_i \ldots s_k)^{-1} \). We claim that to prove (ii), it suffices to check that in (*) every \( B(s_i \ldots s_k)\tau_1w_0P(\text{mod } P) \) is not the big cell in \( G/P \). For, if this property is true, then every \( B(s_i \ldots s_i)\tau_1w_0P(\text{mod } P) \) in (*) is contained in \( X_0 \) (the codimension one Schubert variety in \( G/P \) contains any proper (i.e. \( \neq G/P \)) Schubert variety in \( G/P \)) and (ii) would then follow. Suppose then that
\[ B(s_i \ldots s_i)\tau_1w_0P = Bw_0P(\text{big cell in } G/P) \]

where \( s_i \ldots s_i \) is a subword of \( (s_1 \ldots s_p) \). This implies that
\[ s_i \ldots s_i \tau_1w_0 = w_0\theta, \theta \in W_p \]

i.e. \( s_i \ldots s_i \tau_1 = w_0\theta w_0 = \theta', \theta' \in W_l(P) \)

i.e. \( (s_i \ldots s_i)\theta' = \tau_1, \theta' \in W_l(P) \).
From Lemma 2, it follows then that
\[ X(\tau_1 w_0) = X(s_{i_1} \cdots s_{i_k} w_0). \]

But now \( X(s_{i_1} \cdots s_{i_k} w_0) \supset X(\tau_2 w_0) \) since \( s_{i_1} \cdots s_{i_k} \) is a subword of \( \tau_2 = s_1 \cdots s_p \). Hence \( X(\tau_1 w_0) \supset X(\tau_2 w_0) \), which contradicts the assumption that \( \tau_2 \not\supset \tau_1 \). This concludes the proof of (ii) and hence of Lemma 3.

\[ \square \]

**Lemma 4.** We have the following:

\[ X(\tau w_0) \cap \tau X_0 = \text{union of all Schubert varieties in } X(\tau w_0) \text{ of codimension one} = \text{union of all proper Schubert subvarieties of } X(\tau w_0) \text{ as in Lemma 2}. \]

Equivalently (because of Lemma 3)

\[ (\text{Big cell in } X(\tau w_0)) \cap \tau X_0 \text{ is empty}. \]

(The intersections taken in this lemma are set theoretic).

**Proof.** Now \( X(\tau w_0) \cap \tau X_0 \) is of pure codimension one in \( G/P \). Hence it suffices to prove that

\[ X(\tau w_0) \cap \tau X_0 = \text{union of all proper Schubert subvarieties of } X(\tau w_0). \]

By Lemma 3 if \( \tau_1 \geq \tau \) and \( \tau_1 \neq \tau \)

\[ X(\tau_1 w_0) \subset \tau X_0(\text{for } \tau \not\supset \tau_1). \]

Hence \( X(\tau w_0) \cap \tau X_0 \) contains all the proper Schubert subvarieties of \( X(\tau w_0) \) in \( G/P \). Thus to prove Lemma 4 it suffices to show that

\[ (\text{Big cell in } X(\tau w_0)) \cap \tau X_0 \text{ is empty}. \]

This is easily shown as follows (cf. Prop. A. 4, [12]): we have to show that

\[ B\tau w_0 P \cap \tau X_0 \text{ is empty}. \]

Take the action of \( B \) on \( G/B \) induced by left multiplication and let us compute the isotropy group at \( \tau w_0 \in G/B \):

\[ b\tau w_0 = \tau w_0 b'(b, b' \in B) \text{ i.e. } (\tau w_0)^{-1} b(\tau w_0) \in B. \]
Hence if $B_1$ is the isotropy sub-group at $(\tau w_0)$, we have
\[
B_1 = \{ b \in B/(\tau w_0)^{-1}b(\tau w_0) \in B \}
= T \times \prod_{\alpha} U_{\alpha}/(\tau w_0)^{-1}(\alpha) > 0, \alpha > 0
= T \times \prod_{\alpha} U_{\alpha}/\alpha > 0, \tau^{-1}(-\alpha) > 0 \quad \text{i.e.} \quad \tau^{-1}(\alpha) < 0.
\]

Now $B = B_1 \times B_2$, where
\[
B_2 = \prod_{\alpha} U_{\alpha} \begin{cases} 
\tau^{-1}(\alpha) = \beta > 0, \alpha > 0 \\
\text{i.e.} \alpha = \tau(\beta), \alpha > 0, \beta > 0
\end{cases}
\]
Hence
\[
T \cdot B_2 = B \cap \tau B \tau^{-1}.
\]
Therefore, if $y \in B\tau w_0 B$, we have
\[
y = b_1 \tau w_0 b_2, \quad b_i \in B, \quad b_1 = \tau \epsilon \tau^{-1}, c \in B.
\]
Hence
\[
y = \tau c w_0 b_2; \quad b_2, c \in B,
\]
This implies that
\[
B\tau w_0 B \cap \tau X_0 \text{ is empty}
\]
for otherwise $\tau c w_0 b_2 = \tau \theta, \theta \in X_0$ which implies that $c w_0 b_2 \in X_0$ and this gives that $w_0 \in X_0$ which is a contradiction. Now it is immediate that
\[
B\tau w_0 P \cap \tau X_0 \text{ is empty}
\]
for otherwise
\[
x = b \tau w_0 p \in \tau X_0, \quad b \in B, \quad p \in P
\]
i.e. $xp^{-1} = b \tau w_0 \in \tau X_0$ i.e. $B\tau w_0 B \cap \tau X_0$ is empty-which is a contradiction. Thus Lemma 4 is proved. \qed
Lemma 5. Let $L$ be the line bundle on $G/P$ and $F$ the section of $L$ whose zero set is $X_0$ as in §1 (the space of sections of $L$ gives a realisation of the irreducible representation of $G$ with highest weight $i(\omega)$ in characteristic zero). Let $A_1$ be the linear subspace of $H^0(G/P, L)$ spanned by $\tau \cdot F$, $\tau \in W/W_i(P)$. Then the linear system $A_1$ has no base points.

Proof. We have to show that given $x \in G/P$, there exists $\tau \in W/W_i(P)$ such that $x \notin \tau X_0$. We can suppose that $x$ is in the big cell of a suitable Schubert variety $X(\tau w_0)$, as $G/P$ is the union of Schubert (or Bruhat) cells and distinct Schubert cells are mutually disjoint. By the second part of Lemma 4, it follows that $x \notin \tau X_0$. This proves Lemma 5. □

Remark 1. It is well-known that $\text{Pic } G/P = \mathbb{Z}$, $L$ is ample and generates $\text{Pic } G/P$. Since the linear system $A_1$ in Lemma 5 has no base points, $A_1$ defines a morphism

$$\varphi : G/P \to \mathbb{P}(A_1^*), A_1^* = \text{dual of } A_1.$$ 

We see that $\varphi$ is a finite morphism; this is a consequence of the fact that $L$ is ample, for on a fibre of $\varphi$ the restriction of $L$ is trivial and one would get a contradiction if the dimension of the fibre is strictly greater than zero. In particular we have

$$\dim \text{ Image of } \varphi = \dim G/P.$$

3 Standard monomials

Let $L(\tau)$ denote the restriction of $L$ to the Schubert subvariety $X(\tau w_0)$ of $G/P$ (we endow $X(\tau w_0)$ with the canonical structure of a reduced closed subscheme of $G/P$), $L$ being the ample generator of $\text{Pic } G/P$.

We set:

$$R(\tau) = \bigoplus_{n=0}^{\infty} H^0(X(\tau w_0), L(\tau)^n); R(\tau)_n = H^0(X(\tau w_0), L(\tau)^n)$$

$$R(e) = R = \bigoplus_{n=0}^{\infty} H^0(G/P, L^n), R_n = H^0(G/P, L^n)$$
\(e = \text{element of } W/W_{i(P)}\) corresponding to the class \(W_{i(P)}\)

\[I = W/W_{i(P)}, \ I_r = \{\tau_1 \in I/\tau_1 \geq \tau\}.
\]

\(p_r = \text{the section } \tau \cdot F \text{ of } L \text{ on } G/P (F \text{ as in §1 and Lemma 5}).\)

\(A(\tau) = \text{subalgebra of } R(\tau) \text{ generated by } P_\lambda, \lambda \in I_{\tau}\)

\(A = A(e), e = \text{the element of } I = W/W_{i(P)} \text{ defined by } W_{i(P)}\).

**Definition 2.** An element \(p \in R_m \) (resp. \(R(\tau) m\)) of the form

\[p = p_{\tau_1} \ldots p_{\tau_m}, \tau_i \in I\text{(resp. } I_r), \tau_1 \leq \ldots \leq \tau_m\)

is called a standard monomial in \(I\) (resp. \(I_{\tau}\)) of degree or length \(m\).

**Proposition 1.** Distinct standard monomials in \(I_{\tau}\) are linearly independent (as elements of \(R(\tau)\)). In particular distinct standard monomials in \(I\) are linearly independent.

**Proof.** We prove this by induction on \(\dim X(\tau w_0)\). By definition \(R(\tau)\) is a graded ring and hence it suffices to prove that standard monomials, say in \(R(\tau) m\) are linearly independent. Suppose now that \(\dim X(\tau w_0) = 0\) i.e. \(X(\tau w_0)\) reduces to a point \(x_0 \in G/P\). Then \(I_{\tau}\) reduces to one element, namely \(I_{\tau} = \{\tau\}\) and upto a constant multiple, there is only one standard monomial in \(R(\tau) m\) namely \(p_{\tau}^m\). Further \(p_{\tau}^m \neq 0\), for by Lemma 3, \(p_{\tau}(x_0) \neq 0\). Thus the proposition holds when \(\dim X(\tau w_0) = 0\).

Let us now pass to the general case. Observe that \(R(\tau)\) is an integral domain. Since \(p_{\tau} \neq 0\) in \(R(\tau)\) (Lemma 3), it follows in particular that

\[\lambda p_{\tau} = 0, \ \lambda \in R(\tau) \Rightarrow \lambda = 0.\]

Suppose now that \(p \in R(\tau) m\) can be expressed in the form

\[p = \sum_{(\lambda)} a(\lambda) p_{\lambda_1} p_{\lambda_2} \ldots p_{\lambda_m}\]  

\((*)\)

where \((\lambda) = (\lambda_1 \ldots, \lambda_m), \lambda_1 \leq \ldots \leq \lambda_m\), runs over distinct elements of \(I_{\tau}^m\) and \(a(\lambda) \neq 0, a(\lambda) \in k\). We shall now show that \(p = 0\) leads to a contradiction.
Case (i). Suppose that on the right side of (*) we have a (standard) monomial of the form \( a(\beta)p_{\beta_1} \cdots p_{\beta_m}, \beta_1 > \tau(\beta_1 \neq \tau) \) (of course \( a(\beta) \neq 0 \)).

Let \( q \) denote the restriction of \( p \) to \( X(\beta_1w_0) \). Then \( q \) can be expressed as a sum of standard monomials as follows:

\[
q = \sum_{(\lambda)} a(\lambda)p_{\lambda_1} \cdots p_{\lambda_m}, (\lambda) \text{ as in (*) and } \lambda_1 \geq \beta_1, \quad (**)
\]

i.e. \( q \) is obtained from the right hand side of (*) by cancelling all the terms such that \( \lambda_1 \neq \beta_1 \) (by Lemma \[3\] \( p_{\lambda_1} \) vanishes on \( X(\beta_1w_0) \) when \( \lambda_1 \neq \beta_1 \)). The right hand side of (**) contains at least one term, namely \( a(\beta)p_{\beta_1} \cdots p_{\beta_m} \); besides it consists of distinct standard monomials, as it is obtained from the right hand side of (*) by cancelling some terms. We have

\[
X(\beta_1w_0) \subseteq X(\tau w_0).
\]

Hence by our induction hypothesis, \( q \neq 0 \), so that a fortiori \( p \neq 0 \).

Case (ii). We have only to consider the case, when in (*) \( \lambda_1 = \tau \) for every \( (\lambda) \).

In this case we have \( p = p_{\tau}p' \). Further \( p' \) is a sum of distinct standard monomials, in fact in (*) we have only to cancel the first term \( p_{\lambda_1} = p_{\tau} \) of every monomial. To prove that \( p \neq 0 \), it suffices to prove that \( p' \neq 0 \) since \( R(\tau) \) is an integral domain. Now \( p' \in R(\tau)_{m-1} \) and hence by induction on \( m \) we can suppose that \( p' \neq 0 \). Thus \( p \neq 0 \).

This proves Proposition [1] \[\square\]

Let us recall that we denoted by \( A(\tau) \) (resp. \( A \)) the graded subalgebra of \( R(\tau) \) (resp. \( R \)) generated by \( p_\lambda, \lambda \in I_\tau \) (resp. \( \lambda \in I \)). Set

\[
Y(\tau) = \text{Proj. } A(\tau), Y = \text{Proj. } A(Y = Y(e)).
\]

Then \( Y(\tau) \) is a variety and can be identified with the image of \( X(\tau w_0) \) by the canonical morphism into a projective space defined by the linear system \( A(\tau)_1 = \{p_\lambda/\lambda \in I_\tau \} \). By Lemma [5] the canonical morphism
$X(\tau w_0) \to Y(\tau)$ is a finite morphism and since it is surjective, it follows that $\dim Y(\tau) = \dim X(\tau w_0)$. The graded algebra $A(\tau)$ is generated by $A(\tau)_1$ (=homogeneous elements of degree one in $A(\tau)$). We have canonical surjective homomorphisms

$$A \to A(\tau) \to 0, A(\tau_1) \to A(\tau_2) \to 0, \tau_2 \geq \tau_1$$

induced by the canonical (restriction) homomorphisms

$$R \to R(\tau), R(\tau_1) \to R(\tau_2), \tau_2 \geq \tau_1.$$We thus get canonical immersions

$$Y(\tau) \hookrightarrow Y, Y(\tau_2) \hookrightarrow Y(\tau_1), \tau_2 \geq \tau_1.$$We see that $A(\tau)$ is the homogeneous coordinate ring of $Y(\tau)$ in the projective space associated to the linear system $A(\tau)_1$ (on $X(\tau w_0)$).

**Definition 3.** A subset $T$ of $I$ is said to be a ‘right half space’ (resp. ‘left half space’) if the following property holds:

$$\lambda \in T, \mu \in I \text{ and } \mu \geq \lambda (\text{resp. } \mu \leq \lambda) \Rightarrow \mu \in T.$$We see that intersections and unions of right (resp. left) half spaces are again right (resp. left) half spaces. The complement in $I$ of a right half space is a left half space. If $T$ is a right half space, then

$$T = I_{\tau_1} \cup \ldots \cup I_{\tau_r}$$

where $\tau_1, \ldots, \tau_r$ are the distinct minimal elements of $T$. We set $X(T)$ to be the schematic union

$$X(T) = X(\tau_1 w_0) \cup \ldots \cup X(\tau_r w_0).$$We have then

$$T = \{ \tau \in I / \text{restriction of } p_\tau \text{ to } X(T) \neq 0 \}.$$
Since $X(\tau_1w_0)$ is reduced, $X(T)$ is reduced. We speak of *standard monomials in a right half space* $T$, namely elements of the form

$$p_{\tau_1}p_{\tau_2} \cdots p_{\tau_m}, \tau_1 \in T (\text{then all } \tau_i \in T).$$

From Proposition 1, it follows immediately that distinct standard monomials in $T$ are linearly independent (in fact their restrictions to $X(T)$ are linearly independent). We define $Y(T)$ as the *schematic union*

$$Y(T) = \bigcup Y(\tau_i), \tau_i \text{ minimal elements of } T.$$

We see that $Y(T)$ is *reduced* since $Y(\tau_i)$ is reduced. We note that

$$X(I_\tau) = X(\tau w_0), Y(I_\tau) = Y(\tau), \quad \tau \in I.$$

We denote by $Y_0$ the subvariety of $Y$, which is the image of $X_0$ by the canonical morphism $X \to Y$ i.e. $Y_0 = Y(s)$, $s = S - S_P$. We denote by $\tau Y_0$ the subvariety of $Y$, which is the zero set of $p_\tau$, $\tau \in W/W_{i(P)}$. We denote by $R(T)$ the graded algebra

$$R(T) = \bigoplus_{n=0}^{\infty} H^0(X(T), (L/X(T))^n)$$

and by $A(T)$ the graded subalgebra of $R(T)$ spanned by $\{p_\tau\}, \tau \in T$ (it suffices to take $\tau \in T$). We see that $A(T)$ is the homogeneous coordinate ring of $Y(T)$ (with respect to the projective imbedding of $Y$ considered above) and that

$$A(T) = A(I_\tau) = A(\tau) \text{ when } T = I_\tau.$$

We have canonical surjective homomorphisms

$$A \to A(T) \to 0, A(T_1) \to A(T_2) \to 0; T_2 \subseteq T_1 (T_i \text{ right half spaces}).$$

**Definition 4.** Let $T$ be a right half space. We set

$$\chi(T, m) \neq \# (\text{Set of distinct standard monomials in } T \text{ of degree } m)$$

$\chi(T, 0) = 1$ and $\chi(T, m) = 0, m < 0.$

Lemma 6.  (i) $I_{\tau} - \{\tau\}$ is a right half space; in fact if $T$ is a right half space and $\tau_1, \ldots, \tau_r$ are some distinct element chosen from the minimal elements of $T$, then

$T - \{ (\tau_1, \ldots, \tau_r) \}$ is again a right half space. We have

$$I_{\tau} - \{\tau\} = \bigcup_{\tau_i} I_{\tau_i}$$

where $\tau_i$ are precisely the minimal elements in $I_{\tau}$ such that $l(\tau_i) = l(\tau) + 1$ ($l = \text{length in } W/W_{i(P)}$ or equivalently $l(\tau) = \text{codimension of } X(\tau w_0) \text{ in } G/P$).

(ii) We have (similar to Lemma 4)

$$Y(\tau) \cap \tau Y_0 = Y(T), \ T = I_{\tau} - \{\tau\}$$

in the set theoretic sense.

(iii) $\chi(T_1 \cup T_2, m) = \chi(T_1, m) + \chi(T_2, m) - \chi(T_1 \cap T_2, m)$

(iv) $\chi(I_{\tau}, m) = \chi(I_r - \{\tau\}, m) + \chi(I_{\tau}, m - 1)$

Proof. The proof of (ii) is an immediate consequence of Lemma 4 and the definition of $Y(\tau)$. The proof of the other assertions is straightforward and immediate and is left as an exercise. $\square$

4 Consequences of the hypothesis of generation by standard monomials.

Let $T_0$ be a right half space in $I$. If $T$ is a right half space such that $T \subseteq T_0$, we see that $(T_0 - T)$ is a left half space in $T_0$ i.e.

$$\lambda \in (T_0 - T), \mu \leq \lambda \Rightarrow \mu \in T_0 - T.$$ 

We can similarly define right half spaces $T$ in $T_0$, but this is equivalent to the fact that $T$ is a right half space in $I$, $T \subseteq T_0$. As in the case $T_0 = I$, we note that

$T$ right half space in $T_0 \iff T_0 - T$ is a left half space in $T_0$. 
Proposition 2. Let $T_0$ be a right half space in $I$. Suppose that $A(T_0)$ is spanned by standard monomials in $T_0$. Then we have:

(i) For every right half space $T$ in $T_0$, $A(T)$ is spanned by standard monomials in $T$ and the kernel of the canonical surjective homomorphism (of algebras)

$$A(T_0) \twoheadrightarrow A(T)$$

is the ideal in $A(T_0)$ generated by $\{p_\tau\}, \tau \in T_0 - T$.

(ii) Let $S$ be a left half space in $T_0$, $T = T_0 - S$ and $J(S)$ the ideal in $A(T_0)$ generated by $\{p_\tau\} \tau \in S$. Then the map

$$S \mapsto J(S)$$

from the set of left half spaces in $T_0$ into the set of ideals in $A(T_0)$ takes set intersection into ideal intersection, set union into ideal sum and preserves distributivity properties.

(iii) Consider the map

$$T \mapsto Y(T)$$

from the set of right half spaces in $T_0$ into the set of closed subschemes of $Y(T_0)$. Then this is a bijective map of the set of right half spaces in $T_0$ onto the set of closed subschemes of $Y(T_0)$, each member of which is a (scheme theoretic) union of $Y(\tau), \tau \in T_0$. Further this map takes set union into scheme theoretic union, set intersection to scheme theoretic intersection and preserves distributivity properties. Since unions and intersections of right half spaces in $T_0$ are again right half spaces in $T_0$ and $Y(T)$ is reduced (T right half space in $T_0$), it follows that unions and intersections of $Y(T)$ are again reduced.

Proof. (i) Let $j$ be the canonical homomorphism

$$j : A(T_0) \to A(T).$$
Since $j$ is surjective, it is immediate that $A(T)$ is generated by standard monomials, since $A(T_0)$ has this property by hypothesis. Let $J$ be the ideal in $A(T_0)$ generated by $\{p_{\tau}\}, \tau \in T_0 - T$. By (ii) of Lemma 3, it follows that $J \subset \text{Ker } j$. Hence $j$ induces a canonical homomorphism 
\[ j' : A(T_0)/J \rightarrow A(T). \]

We have to prove that $j'$ is an isomorphism. Let $\theta_1$ be a non-zero element of $A(T_0)/J$. Choose a representative $\theta \in A(T_0)$ of $\theta_1$. Then $\theta$ can be written as a linear combination of standard monomials in $T_0$, but since $p_{\tau} \in J$ for $\tau \in T_0 - T$, in this sum we can cancel those terms which involve $p_{\tau}, \tau \in T_0 - T$. Thus the representative $\theta$ of $\theta_1$ can be chosen so that it is a linear combination of standard monomials in $T$ and $\theta \neq 0$. Now by Prop. 1, it follows that $j(\theta) \neq 0$. This implies that $j'(\theta_1) \neq 0$, which shows that $j'$ is injective. This proves (i).

(ii) The map $J$ in (ii) of Prop. 2 obviously takes set union to ideal sum. On the other hand, to show that $J(S_1) \cap J(S_2) = J(S_1 \cap S_2)$, $S_i$ left half space in $T_0$, we first observe $J(S_1 \cap S_2) \subset J(S_1) \cap J(S_2)$. If $T_1 = T_0 - S_1$ and $T_2 = T_0 - S_2$, we see immediately that $J(S_1) \cap J(S_2)$ vanishes on $X(T)(= X(T_1) \cup X(T_2)), T = T_1 \cup T_2$. On the other hand by (i) $J(S_1 \cap S_2)$ is the ideal of all elements in $A(T_0)$ vanishing on $X(T)$. Hence $J(S_1 \cap S_2) \supset J(S_1) \cap J(S_2)$. This proves the assertion $J(S_1 \cap S_2) = J(S_1) \cap J(S_2)$. The other assertions in (ii) follow easily.

(iii) On account of (i), (iii) is just a reformulation of (ii).

This completes the proof of Prop. 2. □

**Corollary 1.** Let $T_0$ be a right half space in $I$ such that $A(T_0)$ is spanned by standard monomials. Let $\tau$ be an element of $W/W_{i(P)}$ such that $I_{\tau} \subset T_0$. Then the set theoretic intersection in (i), Lemma 3 is in fact scheme theoretic, i.e.

\[ Y(\tau) \cap \tau Y_0 = Y(T), T = I_{\tau} - \{\tau\} \]
where the intersection is scheme theoretic. In particular, the scheme theoretic intersection \( Y(\tau) \cap \tau Y_0 \) is reduced.

**Proof.** This is an immediate consequence of Prop. 2. The scheme theoretic intersection \( Y(\tau) \cap \tau Y_0 \) is defined by the ideal \( J \) in \( A(T_0) \) generated by \( p_{\lambda}, \lambda \in T_0 - I_\tau \) and \( p_\tau \). We observe that \( (T_0 - I_\tau) \cup \{\tau\} \) is a left half space in \( T_0 \), since its complement \( I_\tau - \{\tau\} \) is a right half space (cf. (i), Lemma 6). Hence \( Y(T) \) is the scheme theoretic intersection \( Y(\tau) \cap \tau Y_0 \), \( T = I_\tau - \{\tau\} \). This proves the corollary. □

**Remark 2.** Let \( M \) be the very ample line bundle on \( Y \) (cf. §3 for the definition of \( Y \)) induced by the linear system \( \{p_\tau\}, \tau \in I \). We denote this bundle by \( \mathcal{O}_Y(1) \) and we denote the restriction of this line bundle to \( Y(\tau) \) by \( \mathcal{O}_{Y(\tau)}(1) \). Let now \( T_0 \) be a right half space in \( I \) such that \( A(T_0) \) is generated by standard monomials in \( T_0 \). Let \( I_\tau \subset T_0, \tau \in I \). Then Cor. 1, Prop. 2 gives the exact sequence

\[
0 \to \mathcal{O}_{Y(\tau)}(-1) \to \mathcal{O}_{Y(\tau)} \to \mathcal{O}_{Y(T)} \to 0, \quad T = I_\tau - \{\tau\}. \tag{1}
\]

**Corollary 2.** Let \( \{T_i\}, 1 \leq i \leq r \), be a family of right half spaces in \( I \), such that \( A(T_i) \) is spanned standard monomials, \( 1 \leq i \leq r \). Then if \( T = T_1 \cup \ldots \cup T_r \), \( A(T) \) is also spanned by standard monomials.

**Proof.** By induction on \( r \), obviously it suffices to prove the proposition for the case \( r = 2 \). First we claim that

\[
Y(T_1) \cap Y(T_2) = Y(T_1 \cap T_2) \text{ (scheme theoretically).}
\]

To prove this, consider the ideal \( J \) in \( A(T_1) \) which defines the scheme theoretic intersection \( Y(T_1) \cap Y(T_2) \). Obviously \( J \) contains all \( p_\tau \) for \( \tau \in (T_1 - T_1 \cap T_2) \). By Prop. 2, since \( A(T_1) \) is generated by standard monomials and \( T_1 - T_1 \cap T_2 \) is a left half space in \( T_1 \), it follows that \( A(T_1)/J = A(T_1 \cap T_2) \). This is precisely the above claim.

Let now \( B \) be a commutative ring and \( J_1, J_2 \) two ideals in \( B \). Then one sees easily that the homomorphism \( B \to B/J_1 \oplus B/J_2 \) defined by
\( b \mapsto (b \mod J_1, b \mod J_2) \) induces the following exact sequence of \( B \)-modules

\[
0 \rightarrow B/J_1 \cap J_2 \rightarrow B/J_1 \oplus B/J_2 \rightarrow j \rightarrow 0
\]

where \( j(b_1, b_2) = b_1 - b_2 (\mod J_1 + J_2) \) and \((b_1, b_2)\) in \( B \oplus B \) represents an element of \( B/J_1 \oplus B/J_2 \). If \( J_1 \cap J_2 = 0 \), then this gives

\[
0 \rightarrow B \rightarrow B/J_1 \oplus B/J_2 \rightarrow B/J_1 + J_2 \rightarrow 0. \quad (*)
\]

Let \( J = \text{Spec} \ B \) and \( Z_i \) the closed subschemes of \( Z \), \( Z_i = \text{Spec} \ B/J_i \), \( i = 1, 2 \). Then we have

(i) \( J_1 \cap J_2 = 0 \iff Z = Z_1 \cup Z_2 \) (scheme theoretic union)

(ii) \( \text{Spec} \ B/J_1 + J_2 = Z_1 \cap Z_2 \).

Thus from (*) it follows that if \( Z_i \), \( i = 1, 2 \), are closed subschemes of \( Z \) such that \( Z = Z_1 \cup Z_2 \) (scheme theoretic), then we have the following exact sequence of \( \mathcal{O}_Z \)-modules (patching up \( Z_1 \) and \( Z_2 \) along \( Z_1 \cap Z_2 \))

\[
0 \rightarrow \mathcal{O}_Z \rightarrow \mathcal{O}_{Z_1} \oplus \mathcal{O}_{Z_2} \rightarrow \mathcal{O}_{Z_1 \cap Z_2} \rightarrow 0.
\]

From the above general remark, it follows that we have an exact sequence of \( \mathcal{O}_{Y(T)} \)-modules (\( T = T_1 \cup T_2 \))

\[
0 \rightarrow \mathcal{O}_{Y(T)} \rightarrow \mathcal{O}_{Y(T_1)} \oplus \mathcal{O}_{Y(T_2)} \rightarrow \mathcal{O}_{Y(T_1 \cap T_2)} \rightarrow 0. \quad (2)
\]

By hypothesis

\[
\dim A(T_i)_m = \chi(T_i, m), \quad i = 1, 2
\]

and by Prop. 2 since \( T_1 \cap T_2 \subset T_1 \)

\[
\dim A(T_1 \cap T_2)_m = \chi(T_1 \cap T_2, m).
\]

By (ii) of Lemma 6 it follows that

\[
\chi(T, m) = \dim A(T)_m.
\]

On the other hand, by Prop. 1 the subspace in \( A(T)_m \) spanned by standard monomials is of dimension \( \chi(T, m) \). Hence it follows that \( A(T)_m \) is spanned by standard monomials. This proves Corollary 2 Proposition 2. \( \square \)
Proposition 3. Let $T_0$ be a right half space in $I$ such that $A(T_0)$ is spanned by standard monomials. Then for every right half space $T$ in $T_0$, we have:

(i) $\dim H^0(Y(T), \mathcal{O}_{Y(T)}(m)) = \chi(T, m)$ or equivalently (because of Prop. 2)

$$A(T)_m = H^0(Y(T), \mathcal{O}_{Y(T)}(m)), m \geq 0.$$ 

In particular, if $T_1$, $T_2$ are two right half spaces in $T_0$ such that $T_1 \subset T_2$, then the canonical homomorphism

$$H^0(Y(T_2), \mathcal{O}_{Y(T_2)}(m)) \rightarrow H^0(Y(T_1), \mathcal{O}_{Y(T_1)}(m)), m \geq 0$$

is surjective

(ii) $H^i(Y(T), \mathcal{O}_{Y(T)}(m)) = 0, i > 0, m \geq 0$

Proof. We prove the proposition by induction on $\dim Y(T) (= \dim X(T)$, cf. Remark 1). Let $n = \dim Y(T)$. We claim that it suffices to prove the proposition when $Y(T)$ is of the form $Y(\tau), \tau \in I$. To prove this, since $Y(T)$ is the schematic union of $Y(\tau_i), T = \bigcup_{i=1}^{r} I_{\tau_i}$ ($\tau_i$-the minimal elements of $T$), we see easily that it suffices to prove the following:

$$\begin{cases}
\text{Let } T_1 = I_{\tau_1} \text{ and } T_2 = \bigcup_{i=2}^{r} I_{\tau_i}. \text{ Suppose that (i) and} \\
\text{(ii) above hold for } Y(T_1) \text{ and } Y(T_2); \text{ then they hold for} \\
Y(T), \ T = T_1 \cup T_2.
\end{cases} \quad (*)$$

The claim (*) is an easy consequence of the exact sequence 2 (cf. Cor. 2, Prop. 2), namely the exact sequence of $\mathcal{O}_{Y(T)}$ modules

$$0 \rightarrow \mathcal{O}_{Y(T)} \rightarrow \mathcal{O}_{Y(T_1)} \oplus \mathcal{O}_{Y(T_2)} \rightarrow \mathcal{O}_{Y(T_1 \cap T_2)} \rightarrow 0 \quad (**).$$

We see that $\dim Y(T_1 \cap T_2) \leq (n - 1)$. Hence the proposition is true for $Y(T_1 \cap T_2)$. In particular,

$$H^0(\mathcal{O}_{Y(T_1 \cap T_2)}(m)) = A(T_1 \cap T_2)_m$$
and it is spanned by standard monomials. Hence the canonical map

\[ H^0(\mathcal{O}_{Y(T_1)}(m) \oplus \mathcal{O}_{Y(T_2)}(m)) \to H^0(\mathcal{O}_{Y(T_1 \cap T_2)}(m)) \]  (***)

is surjective for \( m \geq 0 \). Writing the cohomology exact sequence for (**) we get

\[ \dim H^0(\mathcal{O}_{Y(T_1 \cup T_2)}(m)) = \chi(T_1, m) + \chi(T_2, m) - \chi(T_1 \cap T_2, m), \]

which implies (by Lemma 6) that

\[ \dim H^0(\mathcal{O}_{Y(T_1 \cup T_2)}(m)) = \chi(T_1 \cup T_2, m). \]

Thus the assertion (1) of Prop. 3 follows.

Since the map (*** is surjective, we see that the sequence

\[ 0 \to H^1(\mathcal{O}_{Y(T_1 \cup T_2)}(m)) \to H^1(\mathcal{O}_{Y(T_1)}(m) \oplus H^1(\mathcal{O}_{Y(T_2)}(m)), m \geq 0 \] (3)

induced by the cohomology exact sequence of (**) is exact. Further we get the exact sequence

\[ 0 \to H^{i-1}(\mathcal{O}_{Y(T_1 \cap T_2)}(m)) \to H^i(\mathcal{O}_{Y(T)}(m)) \to H^i(\mathcal{O}_{Y(T_1)}(m)) \oplus H^i \]

\( (\mathcal{O}_{T_{Y_2}}(m)) \) for \( i \geq 2, \ m \geq 0 \). Since \( \dim Y(T_1 \cap T_2) \leq (n - 1) \), by the induction hypothesis, we have

\[ H^{i-1}(\mathcal{O}_{Y(T_1 \cap T_2)}(m)) = 0, \ i \geq 2, \ m \geq 0. \]

Thus we get the exact sequence

\[ 0 \to H^i(\mathcal{O}_{Y(T_1 \cup T_2)}(m)) \to H^i(\mathcal{O}_{Y(T_1)}(m)) \oplus H^i(\mathcal{O}_{Y(T_2)}(m)), \begin{cases} i \geq 2 \\ m \geq 0 \end{cases} \]

Combining this with (3) above, we get

\[ H^i(\mathcal{O}_{Y(T)}(m)) = 0, \ i \geq 1, \ m \geq 0. \]

This proves the claim (*) above i.e. it suffices to prove the proposition for \( Y(\tau), \tau \in I \).
Let $T = I_\tau - \{\tau\}$. Tensoring the exact sequence in Remark 2 by $\mathcal{O}_{Y(\tau)}(m)$, we get the exact sequence

$$0 \to \mathcal{O}_{Y(\tau)}(m - 1) \to \mathcal{O}_{Y(\tau)}(m) \to \mathcal{O}_{Y(T)}(m) \to 0, \ m \geq 0. \quad (4)$$

We have $\dim Y(T) = (n - 1)$. By our induction hypothesis, it follows, in particular, that $H^0(\mathcal{O}_{Y(T)}(m)) = A(T)_m$ and that it is spanned by standard monomials. Thus implies that the canonical map

$$H^0(\mathcal{O}_{Y(\tau)}(m)) \to H^0(\mathcal{O}_{Y(T)}(m)),$$  

is surjective. If we set $\lambda_m = \dim H^0(\mathcal{O}_{Y(\tau)}(m))$, writing the cohomology exact sequence for (4) at the $H^0$ level, we get

$$\lambda_m - \lambda_{m-1} = \chi(T, m) \text{ for all } m \text{ (note } \lambda_m = \chi(T, m) = 0, m < 0).$$

On the other hand, by Lemma 6 we get

$$\chi(I_\tau, m) - \chi(I_\tau, m - 1) = \chi(T, m) \text{ for all } m.$$

For $m \leq 0$, we see immediately that $\chi(I_\tau, m) = \lambda_m$. From this it follows that $\chi(I_\tau, m) = \lambda_m$ i.e.

$$\chi(I_\tau, m) = \dim H^0(\mathcal{O}_{Y(\tau)}(m)) \text{ for all } m.$$

Writing the cohomology exact sequence for (4) and using the fact that the proposition holds for $\mathcal{O}_{Y(T)}(m)$ (on account of the inductive hypothesis) and the surjective map above, we deduce easily the following:

$$0 \to H^i(\mathcal{O}_{Y(\tau)}(m - 1)) \to H^i(\mathcal{O}_{Y(\tau)}(m)) \text{ is exact, } i \geq 1, m \geq 0.$$

One knows that $H^i(\mathcal{O}_{Y(\tau)}(m)) = 0, i \geq 1$ and $m$ sufficiently large (Serre’s theorem). Hence by decreasing induction on $m$, we deduce immediately that

$$H^i(\mathcal{O}_{Y(\tau)}(m)) = 0, \ i \geq 1, \ m \geq 0.$$

This concludes the proof of Prop. 3. □
Corollary 1. Let $T_0$ be a right half space in $I$ such that $A(T_0)$ is spanned by standard monomials. Let

$$
\hat{Y}(T) = \text{Spec } A(T), \ T \text{ right half space in } T_0.
$$

Then we have the following:

(i) $\hat{Y}(T)$ is reduced

(ii) Consider the map

$$
T \mapsto \hat{Y}(T)
$$

from the set of right half spaces in $T_0$ into the set of closed subschemes of $\hat{Y}(T_0)$. Then this is a bijective map of the set of right half spaces in $T_0$ onto the set of closed subschemes of $\hat{Y}(T_0)$, each member of which is a (schematic) union of $\hat{Y}(\tau), \tau \in T_0$. Further this map takes set union into scheme theoretic union, set intersection to scheme theoretic intersection and preserves distributivity properties. Since unions and intersections of right half spaces in $T_0$ are again right half spaces in $T_0$ and $\hat{Y}(T)$ is reduced, it follows that unions and intersections of $\hat{Y}(T)$ are again reduced ($T$ right half spaces in $T_0$).

(iii) $\hat{Y}(\tau)$ is normal for $\tau \in I$ such that $I_\tau \subset T_0$. In particular, for such a $\tau$, $Y(\tau)$ is normal. We refer to $\hat{Y}(T)$ as cones over $Y(T)$.

Proof. Since $Y(T)$ is reduced and

$$
A(T) = \bigoplus_{m \geq 0} H^0(\mathcal{O}_{Y(T)}(m)) \quad \text{(by Prop. 3),}
$$

it follows immediately that $\hat{Y}(T)$ is reduced. The assertion (ii) is merely the assertion (ii) of Prop. 2.

Let $\tau \in I$ be such that $I_\tau \subset T_0$. Hence as in the proof of Cor. 1, Prop. 2 it follows that

$$
A(\tau)/_{p_{\tau}A(\tau)} = A(T), \ T = I_\tau - \{\tau\}.
$$
Let $\mathcal{O}_\tau$ be the local ring of $\hat{Y}(\tau)$ at its “vertex” i.e. the point corresponding to the irrelevant maximal ideal of the graded ring $A(\tau)$. Since $A(T)$ is reduced by (i) above, it follows that $\mathcal{O}_\tau / p_\tau \mathcal{O}_\tau$ is reduced. This implies that

$$\text{depth } \mathcal{O}_\tau \geq 2.$$ 

On the other hand, it has been shown by Chevalley [6] that the singularity subset of $Y(\tau)$ is of Codim $\geq 2$ in $Y(\tau)$. It follows that the singular locus of $\mathcal{O}_\tau$ is of Codim $\geq 2$ in $\text{Spec } \mathcal{O}_\tau$. Hence $\hat{Y}(\tau)$ as well as $Y(\tau)$ are normal (note of course that $\hat{Y}(\tau)$ is the cone over $Y(\tau)$ in the usual sense for the imbedding of $Y(\tau)$ in the projective space corresponding to the linear system on $Y$ defined by $A_1$). This proves Cor. 1, Prop. 3. □

Remark 3. Let $T_0$ and $\tau$ be as in Cor. 1, Prop. 3 ($I_\tau \subset T_0$). It should be possible to prove that $\hat{Y}(\tau)$ is Cohen-Macaulay by showing that

$$H^i(\mathcal{O}_{Y(\tau)}(m)) = 0, 0 \leq i < \dim Y(\tau), m < 0 \quad (*)$$

Let $T = I_\tau - \{\tau\}$ and $\tau_i$, $1 \leq i \leq r$, be the minimal element of $T$ so that $Y(\tau_i)$ are the irreducible components of $Y(\tau) \cap \tau Y_0$. For proving $(*)$, following the argument as in Prop. 3 for the case $m \geq 0$ (see for example [13]), it is seen easily that one has to show that

$$Y(\tau_i) \cap Y(\tau_j)(i \neq j) \text{ is of pure Codim 1 in } Y(\tau_i)$$

Equivalently one has to show that (cf. Remark 1)

$$X(\tau_i w_0) \cap X(\tau_j w_0)(i \neq j) \text{ is of Codim 1 in } X(\tau_i w_0).$$

When $P$ is miniscule (cf. §5 below), this has been proved by Kempf (cf. [11]) and a proof has also been shown to the author by Lakshmibai and Musili.

Remark 4. Suppose that $Y(\tau)(\tau \in I)$ is of dimension $n$ and that $A(T)$ is spanned by standard monomials whenever $\dim Y(T) \leq (n - 1)$ ($T$ a right half space in $I$). Then to show that $A(\tau)$ is spanned by standard
monomials, we claim that it suffices to prove that the scheme theoretic intersection \( Y(\tau) \cap \tau Y_0 \) is reduced. For, one has the following exact sequence (cf. exact sequence (1) in Remark 2) what is essential for having this exact sequence is that \( Y(\tau) \cap \tau Y_0 \) is reduced and in Remark 2 this follows from Cor. 1, Prop. 2

\[
0 \rightarrow \mathcal{O}_{Y(\tau)}(m - 1) \rightarrow \mathcal{O}_{Y(\tau)}(m) \rightarrow \mathcal{O}_{Y(T)}(m) \rightarrow 0 \tag{*}
\]

where \( T = I_\tau - \{\tau\} \) (this exact sequence is obtained by tensoring the exact sequence (1) of Remark 2 by \( \mathcal{O}_{Y(\tau)}(m) \)). Then as in the proof of Prop. 3, writing the cohomology exact sequence for (*), we deduce that \( A(\tau) \) is spanned by standard monomials. In particular, if the scheme theoretic intersection \( Y(\tau) \cap \tau Y_0 \) is reduced for every \( \tau \in I \), it will follow that \( A(T) \) is generated by standard monomials for every right half space \( T \) in \( I \).

**Remark 5.** Suppose that for a given \( \tau \in I \) (or more generally a given right half space \( T \) in \( I \)) \( A(\tau) \) is spanned by standard monomials when the ground field is of characteristic zero. Then we claim that \( A(\tau) \) is spanned by monomials when the field is of arbitrary characteristic.

Let \( D \) be a complete discrete valuation ring with quotient field \( K \) of characteristic zero and residue field the (algebraically closed) ground field \( k \), assumed to be of characteristic \( p > 0 \). We know that \( G = G' \otimes_D k \), where \( G' \) is a split semisimple group scheme over \( D \). One knows that the above considerations go through over the base Spec \( D \) (cf. [15], esp. Vol. III). To be more precise, let us note the following:

(i) We have a maximal parabolic subgroup \( P' \) in \( G' \) such that \( P' \otimes k = P \) and \( G'/P' \otimes k = G/P \). Further Pic \( G'/P' \approx \mathbb{Z} \) and it has an ample generator \( L' \) such that \( L' \otimes k = L \), where \( L \) is the ample generator of Pic \( G/P \). We have a canonical section \( F' \in H^0(G'/P', L') \) whose zero set is the Schubert scheme \( X_0' \) of codimension one in \( G'/P' \) with \( X_0' \otimes k = X_0 \). We can also suppose that \( T' \) is a maximal split torus in \( G' \) such that \( T' \otimes k = T \) and that in the \( G' - D \) module \( H^0(G'/P', L') \) (for the notation \( G' - D \) module, see [15]), the \( D \) module spanned by \( F' \) is \( T' \) stable.
(ii) the Weyl group $W$ of $G$ is the Weyl group of the abstract root system associated to the split semi-simple group scheme $G'$. Then one knows that $W_D = N(T')/T'$, where $W_D$ is the constant group scheme over $\text{Spec } D$ associated to the abstract group $W$ (cf. p.168-169, Vol. III, [15]). The parabolic subgroup scheme $P'$ has a structure similar to that of $P$ (cf. §1 and we can talk of the parabolic subgroup scheme $i(P')$, $i = w_0$ (Weyl involution). The Weyl group of $i(P')$ is the constant group scheme (over $\text{Spec } D$) associated to the abstract group $W_{i(P)}$.

(iii) the elements of $W$ can be canonically identified with the $D$-valued points of $W_D$ ($W_D$ being a constant group scheme) and these $D$-valued points of $W_D$ can be lifted (not canonically) to some $D$-valued points of $N(T')$ since the canonical morphism $N(T') \to W_D$ is smooth and $D$ is a complete discrete valuation ring with algebraically closed residue field. If $\tau \in W$, denote by the same $\tau$ the $D$-valued point of $N(T')$ obtained this way. If the $D$-valued point $\tau$ corresponds to an element of the subgroup $W_{i(P')}$ of $W$, we see that $\tau$ fixes the Schubert subscheme $X'_0$ or equivalently $\tau \cdot F' = \lambda F'$ ($\lambda = \text{unit in } D$) (cf. §2 and Lemma 1). Let us denote by $p'_\tau$ the element $p'_\tau = \tau \cdot F'$, $\tau \in W$. Since the $D$-module spanned by $F'$ is $T'$ stable, $p'_\tau$ is well-defined up to a unit (i.e. independent of the above lifting to $D$-valued points in $N(T')$ up to a unit in $D$) and thus up to a unit in $D$, the notation

$$p'_\tau, \quad \tau \in W/W_{i(P)}$$

is justified.

Let us now take up the proof of the assertion in Remark[5] above. Let us denote by $X'(\tau w_0)$ the Schubert subscheme in $G'/P'$ associated to $\tau w_0 \in W$ and by $A'(\tau)$, $R'(\tau)$ the algebras over $D$ similar to $A(\tau)$, $R(\tau)$ (cf. §2). We see that $A'(\tau)$ is the subalgebra of $R'(\tau)$ generated by $\{p_\tau\}$, $\tau \in W/W_{i(P)}$. Suppose that $q \in A'(\tau)_m$ is not standard (over $D$). By hypothesis, $A'(\tau) \otimes_D K$ is spanned (over $K$) by standard monomials.
This implies that
\[ q = \sum_{(\alpha) \in I^m_r} \lambda(\alpha) p_{\alpha_1} \ldots p_{\alpha_m}, \alpha_1 \leq \ldots \leq \alpha_m \]
where \( \lambda(\alpha) \in K \), \( \lambda(\alpha) \neq 0 \) and \((\alpha)\) runs over distinct elements of \( I^m_r \). We can write
\[ \lambda(\alpha) = a(\alpha)/p^n, \]
where the summation on the right side runs over distinct standard monomials. Now \( n \neq 0 \), since otherwise \( q \) is a sum of standard monomials. Hence \( n > 0 \). Reduce \( (1) \) mod \( p \) i.e. read \( (1) \) by taking the images of the elements by the canonical homomorphism \( A'(\tau) \to A(\tau) = A'(\tau) \otimes_D k \). Then we get
\[ 0 = \sum_{(\alpha) \in I^m_r} \bar{a}(\alpha)p_{\alpha_1} \ldots p_{\alpha_m}, \bar{a}(\alpha) \neq 0 \] at least for one \((\alpha)\). (2)
where \( \bar{a}(\alpha) \) denotes the image of \( a(\alpha) \) by the canonical homomorphism \( D \to k \) and the right side runs over distinct standard monomials. This contradicts the fact that standard monomials are linearly independent over \( k \) (cf. Prop. [I]). Thus we conclude that \( A'(\tau) \) is spanned by standard monomials over \( D \). This implies, a fortiori, that \( A(\tau) \) is spanned by standard monomials (over \( k \)) as we have \( A'(\tau) \otimes k = A(\tau) \). This proves the assertion in Remark [5]

5 Minuscule weights and the main theorem

Definition 5. A fundamental weight \( \varpi \) (or the associated parabolic group \( P \)) is said to be minuscule (cf. p. 226, exercise 24, [4]) if any
weight $\theta$ of the irreducible representation $V_1$ with highest weight $\varpi$ in characteristic zero (i.e. if $G'$ is the split group scheme over $\mathbb{Z}$ such that $G \otimes_{\mathbb{Z}} k = G$, then $V_1$ is the irreducible representation of $G' \otimes_{\mathbb{Z}} \mathbb{C}$ with highest weight $\varpi$) is of the form

$$\theta = \tau(\varpi), \tau \in W, W = \text{Weyl group}.$$ 

**Proposition 4** (cf. exercise 24, p. 226, [4]). A fundamental weight $\varpi$ is minuscule if and only if

$$\langle \varpi, \alpha^\vee \rangle = 0, 1 \text{ or } -1, \forall \alpha \in \Delta : (\alpha^\vee \text{ coroot of } \alpha).$$

Further, if $\varpi$ is minuscule, $X(\tau \omega_0), \tau \in W/W_{r(P)}$ a Schubert variety in $G/P$ and $Y$ a Schubert variety which is an irreducible component of $X(\tau \omega_0) \cap \tau X_0$ (cf. Lemma [4]), then the multiplicity of this intersection along $Y$ is 1.

**Proof.** Let $\alpha \in \Delta^+$ (positive root) and $\varpi$ be minuscule. One has to show that $\langle \varpi, \alpha^\vee \rangle = 0$ or 1. One knows that $\langle \varpi, \alpha^\vee \rangle$ is an integer $\geq 0$ (cf. Théorème 3, Chap. VII-9, [14]); further by taking the 3-dimensional Lie algebra generated by $X_\alpha, Y_\alpha$ and $H_\alpha$ (notations as in [14]) and using Theorem 1, Chap. IV-3 especially its Corollary 1, (b) (cf. [14]), we see that $(\varpi - r\alpha)$ is also a weight of $V_1$ where $r$ an integer $0 \leq r \leq \langle \varpi, \alpha^\vee \rangle$.

Suppose now that $\langle \varpi, \alpha^\vee \rangle > 1$. Take $r$ such that $0 < r < \langle \varpi, \alpha^\vee \rangle$ Then $q = \varpi - r\alpha$ is a weight of $V_1$. We claim that

$$(q|q) < (\varpi/\varpi)(\text{notation as in [4]})$$

for

$$(\varpi - r\alpha/\varpi - r\alpha) = (\varpi/\varpi) + r^2(\alpha/\alpha) - 2(\varpi/\alpha)r$$

$$= (\varpi/\varpi) + r^2(\alpha/\alpha) - r(\alpha/\alpha)(\varpi, \alpha^\vee)$$

$$= \begin{cases} 2(\varpi/\alpha) \\ (\alpha, \alpha) \end{cases}$$

$$= (\varpi/\varpi) + (\alpha/\alpha)[r^2 - r(\varpi, \alpha^\vee)].$$
Since $0 < r < \langle \varpi, \alpha^\vee \rangle$, we deduce that

$$r^2 - r\langle \varpi, \alpha^\vee \rangle < 0$$

This proves the claim that $(q/q) < (\varpi, \varpi)$. But since $\varpi$ is minuscule, $q = \tau(\varpi)$, $\tau \in W$, which implies, in particular, that $(q/q) = (\varpi, \varpi)$. This leads to a contradiction to the hypothesis that $\langle \varpi, \alpha^\vee \rangle > 1$. Thus we see that $\langle \varpi, \alpha^\vee \rangle = 0$ or $1$.

Suppose now that $\varpi$ is a fundamental weight, such that $\langle \varpi, \alpha^\vee \rangle = 0$, $1$ or $-1$ $\forall \alpha \in \Delta$.

Then we see that for any $\tau \in W$, we have

$$\langle \tau(\varpi), \alpha^\vee \rangle = 0, 1 \text{ or } -1.$$

Let $v \in V_1$ be the element with highest weight $\varpi$. Then one knows that

$$Y_{\beta_1}^{m_1} \ldots Y_{\beta_k}^{m_k} v, m_i \in N, \beta_i \in \Delta^+, (c.f. \text{ Prop. 2, VII - 3, [14]})$$

generate $V_1$ and one has to show that if $Y_{\beta_1}^{m_1} \ldots Y_{\beta_k}^{m_k} v \neq 0$, then the weight of this element is of the form $\tau(\varpi)$, $\tau \in W$. By a simple induction argument, we see that it suffices to show that if $v' \in V_1$, $v' \neq 0$ and of weight $\tau(\varpi)$, $\tau \in W$ and if $Y_{\beta_i} v' \neq 0$, then $Y_{\beta_i} v'$ is of weight $\tau'(\varpi)$ for some $\tau' \in W$. Now $v'$ is the highest weight vector for a suitable conjugate of the Borel subalgebra and $\beta_i$ can be supposed to be positive with respect to this Borel subalgebra. Thus we can suppose without loss of generality, that $\tau = \text{ Identity i.e. } v = v'$. We see that $\langle \varpi, \beta_i^\vee \rangle \neq 0$, for

$$\langle \varpi, \beta_i^\vee \rangle = 1 \text{ and then the weight of } Y_{\beta_i} v \text{ is } \varpi - \beta_i = \varpi - \langle \varpi, \beta_i^\vee \rangle \beta_i = s_{\beta_i}(\varpi).$$

This proves the first assertion of (Prop. 4).

The last assertion of Prop. 4 is an immediate consequence of Chevalley’s multiplicity formula (cf. [8], p. 78, Cor. 1, Prop. 1.2), since by this formula, this required multiplicity is of the form

$$\langle \varpi, \alpha^\vee \rangle \text{(or perhaps } \langle i(\varpi), \alpha^\vee \rangle), \alpha \in \Delta^+$$
and $\varpi$ is minuscule if and only if $i(\varpi)$ is minuscule ($i$ = Weyl involution).

This proves Prop. 4. □

**Remark 6.** Suppose that the base field is of characteristic zero and $\varpi$ is minuscule. Then

$$R(\tau) = A(\tau), \forall \tau \in W/W_{i(P)}.$$  

In particular, the canonical morphism $X(\tau w_0) \rightarrow Y(\tau)$ is an isomorphism (cf. beginning of §3 for the definition of $R(\tau), A(\tau)$).

**Proof.** Since $R_m = H^0(G/P, L^m)$ is known to be irreducible with highest weight $m i(\varpi)$ (Borel-Weil theorem), the canonical $G$-homomorphism

$$\underbrace{R_1 \otimes \ldots \otimes R_1}_{m \text{ times}} \rightarrow R_m$$

is surjective. This shows that $R_1$ generates $R$. Since $i(\varpi)$ is minuscule, the weights of $R_1$ are of the form $\tau i(\varpi), \tau \in W/W_{i(P)}$. Now $\tau i(\varpi)$ is the “highest weight” for a suitable conjugate of the Borel subgroup $B$ of $G$, which shows that the linear subspace of $R_1$ with weight $\tau i(\varpi)$ is of dimension one and hence coincides with the one dimensional subspace spanned by $p_{\tau}$. This shows that $R = A$. The general case follows from a result of Demazure (cf. Theorem 1 [8], p. 84), namely that the canonical map

$$H^0(G/P, \mathcal{O}_{G/P}(m)) \rightarrow H^0(X(\tau w_0), \mathcal{O}_{X(\tau w_0)}(m))$$

is surjective. □

**Remark 7.** We see that if $G$ is type $A_n$, every fundamental weight is minuscule. Looking at the tables in [4], we have the following:

(i) $G$ of type $B_n$, $\varpi$ is minuscule $\Leftrightarrow$ $\varpi = \varpi_n$ i.e. $\varpi$ corresponds to the “right end root” (in the Dynkin diagram)

(ii) $G$ of type $C_n$, $\varpi$ is minuscule $\Leftrightarrow$ $\varpi = \varpi_1$ i.e. $\varpi$ corresponds to the “left end root”.
(iii) $G$ of type $D_n$, $\varpi$ is minuscule $\iff \varpi = \varpi_1$ or $\varpi_{n-1}$ or $\varpi_n$ i.e. $\varpi$ corresponds to the “extreme end roots”.

(iv) $G$ of type $E_6$, $\varpi$ is minuscule $\iff \varpi = \varpi_1$ or $\varpi_6$ i.e. $\varpi$ corresponds to the “left or right end root”.

(v) $G$ of type $E_7$, $\varpi$ is minuscule $\iff \varpi = \varpi_7$ i.e. $\varpi$ corresponds to the “right end root”.

(vi) there are no minuscule weights, when $G$ is of type $E_8$, $F_4$ or $G_2$.

**Proposition 5.** Suppose that the base field is of characteristic zero and $\varpi$ is minuscule. Then $R(\tau) = (A(\tau))$ is spanned by standard monomials in $I_\tau$, $\tau \in W/W_i(P)$.

**Proof.** We prove this by induction on $\dim X(\tau w_0)$. When $\dim X(\tau w_0) = 0$, the required fact is immediate. Now by Remark 4, it suffices to check that the scheme-theoretic intersection $X(\tau w_0) \cap \tau X_0$ is reduced. Now by Demazure’s results, $X(\tau w_0)$ is Cohen-Macaulay (cf. Cor. 2, Theorem 1, [8], p. 84-85). Hence the scheme theoretic intersection $X(\tau w_0) \cap \tau X_0$ is also Cohen-Macaulay. Now by (ii) of Prop. 4, the scheme theoretic intersection $X(\tau w_0) \cap \tau X_0$ is reduced at the generic points of its irreducible components. It follows that $X(\tau w_0) \cap \tau X_0$ is reduced and hence Prop. 5 follows. $\square$

**Theorem 1.** Suppose that the fundamental weigh $\varpi$ is minuscule. Then if $T$ is a right half space in $I$, we have (the characteristic of the ground field $k$ being arbitrary):

(i) $A(T)$ is spanned by standard monomials in $T$;

(ii) $A(T) = R(T)$;

(iii) the line bundle $L$ on $G/P$ is very ample;

(iv) $H^i(X(T), \mathcal{O}_{X(T)}(m)) = 0$, $i > 0$, $m \geq 0$;
(v) Consider the map

\[ T \mapsto X(T) (\text{resp. } \hat{X}(T) - \text{ cone over } X(T)) \]

from the set of right half spaces in \( I \) into the set of closed subschemes of \( G/P \) (resp. \( \hat{G}/P \)). This is a bijective map of the set of right half spaces in \( I \) onto the set of closed subschemes of \( G/P \) (resp. \( \hat{G}/P \)), each member of which is a schematic union of \( X(\tau) \) (resp. \( \hat{X}(\tau) \)), \( \tau \in I \). Further this map takes set union into scheme theoretic union, set intersection into scheme theoretic intersection and preserves distributivity properties. Scheme theoretic unions and intersections of \( X(T) \) (resp. \( \hat{X}(T) \)) are reduced;

(vi) \( X(\tau w_0) \) (in fact the cone \( \hat{X}(\tau w_0) \)) is normal (in fact, \( \hat{X}(\tau w_0) \) is also Cohen–Macaulay, cf. Remark 3 above);

(vii) \( X(\tau w_0) \cap \tau X_0 \) is reduced.

\textbf{Proof.} By Prop. 5, \( A(\tau) \) is spanned by standard monomials in \( I_{\tau}, \tau \in W/W_i(P) \), when the ground field is of characteristic zero. Hence by Remark 5 the same holds when the ground field is of arbitrary characteristic. Now by Cor. 2 Prop. 2 it follows that \( A(T) \) is spanned by standard monomials in \( T, T \) being any right half space in \( I \). This proves (i).

Now \( H^1(X(T), \mathcal{O}_{X(T)}(m)) = 0 \), when \( m \) is sufficiently large. Hence \( R(T)_m = H^0(X(T), \mathcal{O}_{X(T)}(m)) \) is obtained by “reduction mod \( p \)” of the same space in characteristic zero (note that \( X(\tau w_0), X(T) \) can be constructed as schemes over \( \mathbb{Z} \)), when \( m \) is sufficiently large. In particular, we get

\[ \dim R(T)_m = \chi(T, m), m \gg 0 \]

since by Prop. 5 and Cor. 2 Prop. 2 \( R(T)_m \) is spanned by standard monomials in \( T \) when the ground field is of characteristic zero. On the other hand

\[ \dim A(T)_m = \chi(T, m), \forall m \]

because of (i). Hence, we get

\[ A(T)_m = R(T)_m, m \gg 0. \]
Since $A(T)_1$ generates $A(T)$, it follows that the canonical morphism

$$X(T) = \text{Proj}R(T) \to Y(T) = \text{Proj}A(T)$$

is an isomorphism; in particular $L|_{X(T)}$ is very ample. Since (i) holds and $X(T) = Y(T)$, we deduce that

$$A(T)_m = R(T)_m$$

by (i), Prop. 3. This proves (ii) and (iii).

The assertions (iv), (v) and (vi) and (vii) are taken from Prop. 1, its Cor. 1, Prop. 3 and its Cor. 1. □

**Corollary 1.** Let $\varpi$ be minuscule. Suppose that $p_{\beta_1}p_{\beta_2}$ is a quadratic monomial which is not standard, $\beta_i \in I$. Then we have a unique relation

$$p_{\beta_1}p_{\beta_2} = \sum_{(\alpha) \in I^2} \lambda(\alpha)p_{\alpha_1}p_{\alpha_2}; \alpha_1 \leq \alpha_2 \text{ and } \lambda(\alpha) \in k, \lambda(\alpha) \neq 0 \quad (*)$$

where on the right side $(\alpha)$ runs over distinct elements of $I^2$ of the form

(i) $\alpha_1 \leq \beta_1, \alpha_1 \neq \beta_1; \alpha_1 \leq \beta_2, \alpha_1 \neq \beta_2$

(ii) $\alpha_2 \geq \beta_1, \alpha_2 \neq \beta_2; \alpha_2 \geq \beta_2, \alpha_2 \neq \beta_2$.

**Proof.** By Theorem 1 $p_{\beta_1}p_{\beta_2}$ can be expressed uniquely as a sum of standard monomials. We shall now show that if a non-standard monomial $p_{\beta_1}p_{\beta_2}$ is expressed as a sum of standard monomials (even without assuming that $\varpi$ is minuscule), then the properties (i) and (ii) above are satisfied.

Suppose then $\alpha_1 \not\leq \beta_1$. Restrict (*) to the Schubert variety $X(\alpha_1w_0)$. Then the restriction of $p_{\beta_1}$ to $X(\alpha_1w_0)$ is zero (cf. Lemma 3) and we get

$$0 = \lambda(\alpha)p_{\alpha_1}p_{\alpha_2} + \sum \ldots$$

which contradicts the linear independence of standard monomials (cf. Prop. 1)). Thus we see that $\alpha_1 \leq \beta_1$. Suppose that $\alpha_1 = \beta_1$; since $\beta_1, \beta_2$ are not comparable, we deduce that $\beta_2 \not\leq \alpha_1$. Again the restriction of
$p_{\beta_2}$ to $X(\alpha_1 w_0)$ is zero and restricting (*) to $X(\alpha_1 w_0)$ we get a contradiction. Thus we deduce that $\alpha_1 \leq \beta_1$, $\alpha_1 \neq \beta_1$. Similarly, we deduce that $\alpha_1 \leq \beta_2$; $\alpha_1 \neq \beta_2$.

To prove (ii), we observe that $\tau_i \cdot p_{\tau_2} = p_{\tau_1 \tau_2}$, $\tau_i \in W$, (this is well defined only up to a constant, see the discussion preceding Lemma 1). Transforming (*) by left action by the element $w_0$ (or to be precise by a representative of $w_0$ in $N(T)$), we get

$$p_{w_0 \beta_1} p_{w_0 \beta_2} = \sum_{(\alpha) \in I^2} \mu(\alpha) p_{w_0 \alpha_2} p_{w_0 \alpha_1}, \quad (**),$$

where $(\alpha)$ runs over the same set of elements as in (*) and $\mu(\alpha) \neq 0$. We see easily that $\alpha_1 \leq \alpha_2 \iff w_0 \alpha_1 \geq w_0 \alpha_2$ (cf. Definition 1).

Hence the right side of (**) also runs over distinct standard monomials and the left side of (**) is not standard. Hence applying (i), we get for example

$$w_0 \alpha_2 \leq w_0 \beta_1; w_0 \alpha_2 \neq w_0 \beta_1$$

and this implies $\alpha_2 \geq \beta_1$, $\alpha_2 \neq \beta_1$. This proves (ii) and completes the proof of the corollary. \hfill \Box

**Remark 8.** In the proof of Theorem the work of Demazure [8], especially his result that the Schubert varieties are Cohen-Macaulay in characteristic zero, has been used. A more direct proof would be along the following lines: When $\sigma$ is minuscule and the base field is of characteristic zero, suppose one is able to check (probably using Weyl’s or Demazure’s character or dimension formula) directly that

$$\dim H^0(G/P, O_{G/P}(2)) = \chi(I, 2).$$

Then this implies that given a non-standard quadratic monomial $p_{\beta_1} p_{\beta_2}$, this can be expressed as in (*), Cor. Theorem as a linear combination of standard monomials (base field is of characteristic zero) and we have seen in the proof of this corollary that the properties (i) and (ii) of
Cor. Then Theorem follow then automatically. Then by the argument as in or (Prop. 3. 1, p. 153 [13]), we conclude that the standard monomials span \( R \), and by Remark the same conclusion holds in arbitrary characteristic. Once we have this, Theorem follows from Prop. and Prop. 3.

Varieties with No Smooth Embeddings

By M.V. Nori

This paper is based essentially on the following idea: A scheme $X$ which has no effective Cartier divisors cannot be embedded in a smooth scheme, or for that matter, even in a smooth algebraic space ([1], p. 326). For, given any such embedding of $X$, one could find plenty of such divisors on the ambient space which do not contain $X$, and hence their restrictions to $X$ would be effective and locally principal again. However, this says nothing about embedding $X$ in a complex manifold (not necessarily algebraic).

I thank Simha very heartily for providing the incentive to look for examples of such varieties; also for discussing the problem with me in some detail.

One may construct such a scheme $X$ quite simply as follows:

Take irreducible curves $C_1$ and $C_2$ of different degrees in $\mathbb{P}^n$, such that there is a birational isomorphism $f : C_1 \rightarrow C_2$, and identify the points $x$ and $f(x)$, where $x \in C_1$, to get a quotient variety $X$ of $\mathbb{P}^n$ with the following properties:

(A) $X$ is a reduced irreducible scheme and $\varphi : \mathbb{P}^n \rightarrow X$ is the normalisation map,

(B) $\varphi = \varphi \circ f$ for all points of $C_1$, and $\varphi$ maps $C_1$ birationally onto its image $C = \varphi(C_1)$,

(C) any line bundle $L$ on $X$ lifts to the trivial line bundle on $\mathbb{P}^n$, and therefore $X$ is not projective,

(D) however, any finite set of points of $X$ is contained in an affine open set, and finally,
(E) $X$ has no smooth embeddings.

To prove (C), note that the degrees of $\varphi^*(L)|C_1$ and $\varphi^*(L)|C_2$ both coincide with the degree of $L|C$, and are therefore equal. But $\varphi^*(L)$ is $\mathcal{O}_{P^n}(k)$ for some integer $k$, and therefore the degrees in question are $kd_1$ and $kd_2$ respectively, where $d_1$ and $d_2$ are the degrees of $C_1$ and $C_2$. Now, $d_1 \neq d_2$ by assumption, implying that $k$ is equal to zero and thereby settling the fact that $\varphi^*(L)$ is trivial.

Now (E) follows. Because, otherwise, $X$ possesses an effective line bundle $L$ which lifts to $\varphi^*(L)$, an effective line bundle!

The rest of the properties follow from the explicit construction of $X$, the details of which are probably well-known (compare with Theorem 6.1 of ‘Algebraization of formal moduli...’ by M. Artin, Annals of Math. (1970), vol. 91) but follow nevertheless.

All schemes considered are of finite type over an algebraically closed field $k$.

Call a scheme a $F$-scheme if every finite set of (closed) points is contained in an affine open set.

**Lemma 1.** If $Y \to Y'$ is a finite morphism and $Y'$ is an $F$-scheme, so is $Y$.

**Proof.** Obvious. □

**Lemma 2.** If $Y \to Z$ is a closed immersion, $g : Y \to Y'$ a finite morphism, and $Z$ and $Y'$ are $F$-schemes, then given any finite set $S \subset Z$, there exists an affine open subset $U$ of $Z$ which contains $S$, such that $g$ restricts to a finite morphism from $Y \cap U$ onto its image.

**Proof.** Replace $S$ by $T = S \cup g^{-1}g(S \cap Y)$ which is also finite and let $W_1$ be an affine open set that contains it. Because $Y'$ is an $F$-scheme, there is an affine open set $V'$ that contains $g(S \cap Y)$. Now, $g^{-1}(V') \cap W_1$ is a neighbourhood of $T \cap Y$ in $Y$; so it follows that there is an affine open $W_2 \subset W_1$ such that $W_2 \cap Y$ is contained in $g^{-1}(V')$, and $T \subset W_2$. Also, $g^{-1}g(S \cap Y)$ is contained in $W_2$, which means that there is a $h$ in the co-ordinate ring of $V'$ such that $g$ restricts to a finite morphism from $D(h \circ g) \subset W_2 \to D(g) \subset V'$. Also, there exists $f$ defined on $W_2$.
such that $f = h \circ g$ when restricted to $Y \cap W_2$, and $T \subset D(f)$. Putting $D(f) = U$ proves the lemma. □

**Lemma 3.** If $g : Y \to Y'$ is a finite morphism, and $Y$ is an $F$-scheme, so is $Y'$.

*Proof.* Assume, by induction, that the lemma has been proved when $\dim Y \leq n - 1$. □

**Step 1.** $Y$, $Y'$ irreducible, reduced, and have the same quotient field, with $\dim Y = n$.

Let $I$ be the conductor of the morphism; denote by $A$ and $A'$ the closed subschemes defined by $I$ in $Y$ and $Y'$ respectively. Then $A$ is an $F$-scheme of dimension $\leq n - 1$; by induction, $A'$ is an $F$-scheme too, so one may appeal to Lemma 2 with $A'$, $A$, $Y$ in place of $Y'$, $Y$, $Z$. Now, let $S'$ be any finite set in $Y'$, $S$ its inverse image in $Y$ and $U$ an affine open set containing $S$ such that $U \cap A \to g(U \cap A) \subset A'$ is a finite morphism. This is merely equivalent to saying that $g^{-1}g(U \cap A) = U \cap A$, from which it follows that $g^{-1}g(U) = U$, so that $U \to g(U)$ is a finite morphism, proving that $g(U)$ is affine. Obviously, $g(U)$ contains $S'$, finishing the proof that $Y'$ is an $F$-scheme.

**Step 2.** $Y$ and $Y'$ both irreducible and normal. There is a factoring $Y \to Y'' \to Y'$ with $Y \to Y''$ purely inseparable and $Y'' \to Y'$ separable, with $Y''$ normal too. That $Y''$ an $F$-scheme implies $Y$ an $F$-scheme is classical (it involves identifying $Y''$ with the quotient of a certain $F$-scheme by a finite group $G$) and we omit it. Also, $Y \to Y''$ is a homeomorphism in the Zariski topology, proving that $Y'$ is an $F$-scheme too.  

**Step 3.** $Y$ and $Y'$ irreducible.

This is proved by replacing $Y$ by its normalisation and putting step 1 and step 2 together.

**Step 4.** The general case.
Let $Z'$ be any irreducible component of $Y'$ and $Z$ any irreducible component of $g^{-1}(Z')$ that maps onto $Z'$. Because $Z$ is an $F$-scheme, by step 3 $Z'$ is a $F$-scheme. So the lemma would be proved if one has

**Sub-Lemma.** If $Y = Y_1 \cup Y_2$ where $Y_1$ and $Y_2$ are closed subschemes, then $Y$ is an $F$-scheme if and only if $Y_1$ and $Y_2$ are both $F$-schemes.

**Proof.** Assume that $Y_1$ and $Y_2$ are $F$-schemes, and let $S$ be any finite set in $Y$. With the given information, it is a trivial matter to find affine open subsets $U_i$ of $Y_i$ containing $S \cap Y_i$ for $i = 1, 2$, such that $U_1 \cap Y_2 = U_2 \cap Y_1$, by choosing affine open $V_i$ in $Y_i$ containing $S \cap Y_i$ and then taking convenient principal affine open subsets of each. Now, $U_1$ and $U_2$ are closed in $U = U_1 \cup U_2$, proving that $U$ is affine (because a scheme is affine if and only if each irreducible component is affine). □

**Proposition.** Given an $F$-scheme $Z$, a closed subscheme $Y$, a finite surjective morphism $g : Y \rightarrow Y'$ which induces a monomorphism on co-ordinate rings, there is a unique commutative diagram

$$
\begin{array}{ccc}
Y & \rightarrow & Z \\
g \downarrow & & \downarrow f \\
Y' & \rightarrow & Z'
\end{array}
$$

with:

(a) $Z'$ is an $F$-scheme, $f$ is finite and induces a monomorphism on co-ordinate rings, $Y' \rightarrow Z'$ is a closed immersion, and

(b) the ideal $I$ that defines $Y'$ in $Z'$ remains an ideal in $f_*(O_Z)$, in fact the ideal that defines $Y$ in $Z$.

**Proof.** First assume that $Z$ is affine, in which case $Y$ and $Y'$ are affine too. Let $A$, $A/I$, $B$ be their co-ordinate rings, and then $B \subset A/I$ in a natural way. Let $j : A \rightarrow A/I$ be the standard map, and put $A' = j^{-1}(B)$, $\text{spec } A' = Z'$. That $Z'$ has the required properties follows immediately, as does the fact that if $Z$ were replaced by an open subset $U$ such that
$g^{-1}g(U \cap Y) = U \cap Y$, $Z'$ would be replaced by $U' = f(U)$ which is an open subset.

This guarantees the existence of $Z'$ once it has been shown that $Z$ can be covered by affine open subsets $U$ such that $g^{-1}g(U \cap Y) = U \cap Y'$. By Lemma 3, $Y'$ is an $F$-scheme, so it follows by Lemma 2 that such open sets cover $Z$, and in fact can be chosen to contain any finite set of points, proving that $Z'$ exists and is an $F$-scheme.

To come back to the previous problem, put $\mathbb{P}^n = Z$, and $Y = C_1 \cup C_2$ in $\mathbb{P}^n$. Let $D_i$ be the normalisation of $C_i$ and $\tilde{f} : D_1 \to D_2$ be the lift of the rational map $f : C_1 \to C_2$. There are several candidates for a commutative diagram:

\[
\begin{array}{ccc}
D_1 & \oplus & D_2 \\
\downarrow & & \downarrow \\
D_2 & \rightarrow & Y'
\end{array}
\]

among which there is a best one, for which,

(I) $h_*(O_{D_2}/O_{Y'})$ injects into $h'_*(O_{D_1 \oplus D_2})/O_{Y'}$,

(II) $h$ is birational.

Applying the above proposition, with $Z$, $Y$ and $Y'$ as above, one gets the variety $X$ mentioned in the introduction.

A final remark: $X$ has no line bundles at all if $C_1$ and $C_2$ are chosen suitably!

Let $i_1$ and $i_2$ be the composites $D_1 \to C_1 \to \mathbb{P}^n$ and $D_2 \to C_2 \to \mathbb{P}^n$ respectively. Assume that there is a point $P$ of $D_1$ such that $i_1(P) = i_2f(P)$. Then

(F) $X$ is simply connected (follows from a careful application of Van Kampen’s theorem), and

(G) Pic $X = 0$.

A rather neat example is provided by taking a conic $C_1$ and a tangential line $C_2$ in the projective plane and associating to a point $P$ on
C₁ the point of intersection Q of C₂ and the tangent line to C₁ at P; the properties (A) to (G) can be verified directly in this case.

[Added in Proof: Such varieties were also constructed by G. Horrocks on slightly different lines; see: ‘Birationally ruled surfaces without embeddings in regular schemes’, by G. Horrocks, *J. Lond, Math. Soc.*, Vol. III (1971)]

References

Some Footnotes to the Work of
C. P. Ramanujam

By D. Mumford

THIS PAPER consists of a series of remarks, each of which is connected in some way with the work of Ramanujam. Quite often, in the last few years, I have been thinking on some topic, and suddenly I realize—Yes, Ramanujam thought about this too—or—This really links up with his point of view. It is uncanny to see how his ideas continue to work after his death. It is with the thought of embellishing some of his favourite topics that I write down these rather disconnected series of results.

I

The first remark is a very simple example relevant to the purity conjecture (sometimes called Lang’s conjecture) discussed in Ramanujam’s paper [10]. The conjecture was—let

\[ f : X^n \to Y^m \]

be a proper map of an \( n \)-dimensional smooth variety onto an \( m \)-dimensional smooth variety with all fibres of dimension \( n - m \). Assume the characteristic is zero. Then show

\[ \{ y \in Y | f^{-1}(y) \text{ is singular} \} \]

has codimension one in \( Y \). When \( n = m \), this result is true and is known as “purity of the branch locus”; when \( n = m + 1 \), it is also true and
was proven by Dolgačev, Simha and Ramanujam. When \( n = m + 2 \), Ramanujam describes in [10] a counter-example due to us jointly. Here is another counter-example for certain large values of \( n - m \).

We consider the following very special case for \( f \). Start with \( Z' \subset P^m \) an arbitrary subvariety. Let \( \hat{P}^m \) be the dual projective space—"the space of hyperplanes in \( P^m \). The dual variety \( \hat{Z} \subset \hat{P}^m \) is, by definition the Zariski-closure of the locus of hyperplanes \( H \) such that, at some smooth point \( x \in Z', T_{x,H} \supset T_{x,Z} \). It is apparently well known, although I don’t know a reference, that in characteristic 0,

\[
\hat{Z} = Z.
\]

Consider the special case where \( Z \) is smooth and spans \( P^m \). Then we don’t need to take the Zariski-closure in the above definition and, in fact, the definition of \( \hat{Z} \) can be reformulated like this:

Let

\[
I \subset P^m \times \hat{P}^m
\]

be the universal family of hyperplanes, i.e., if \((X_0, \ldots, X_m)\), resp. \((\xi_0, \ldots, \xi_m)\) are coordinates in \( P^m \), resp. \( \hat{P}^m \), then \( I \) is given by

\[
\sum \xi_i X_i = 0.
\]

Let

\[
X = I \cap (Z' \times \hat{P}^m).
\]

Note that \( I \) and \( Z' \times \hat{P}^m \) are smooth subvarieties of \( P^m \times \hat{P}^m \) of codimension 1 and \( m - r \) respectively. One sees immediately that they meet transversely, so \( X \) is smooth of dimension \( m + r - 1 \). Consider

\[
p_2 : X \to \hat{P}^m.
\]

Its fibres are the hyperplane sections of \( Z \), all of which have dimension \( r - 1 \). Thus \( p_2 \) is a morphism of the type considered in the conjecture. In this case

\[
\{ \xi \in \hat{P}^m | p_2^{-1}(\xi) \text{ singular} \} = \{ \xi \in \hat{P}^m | \text{ if } \xi \text{ corresponds to } H \subset P^m, \]

then $\mathbf{Z}.\mathbf{H}$ is singular\}

$$= \hat{\mathbf{Z}}.$$ 

Thus the conjecture would say that the dual $\hat{\mathbf{Z}}$ of a smooth variety $\mathbf{Z}$ spanning $\mathbf{P}^m$ is a hypersurface.

I claim this is false, although I feel sure it can only be false in very rare circumstances. In fact, I don’t know any cases other than the following example where it is false\footnote{M. Reid has indicated to me another set of examples: Suppose $Z = \mathbf{P}(E)$ where $E$ is a vector bundle of rank $s$ on $y'$, so $r = s + t - 1$, and the fibres of $\mathbf{P}(E)$ are embedded linearly. Then if $s \geq t + 2$, $\hat{\mathbf{Z}}$ is not a hypersurface.} Simply take

$$\mathbf{Z}' = [\text{Grassmannian of lines in } \mathbf{P}^{2k}, k > 1].$$ 

Here $r = 2(2k - 1)$, $m = k(2k + 1) - 1$ and the embedding $i : \mathbf{Z}' \subset \mathbf{P}^m$ is the usual Plücker embedding. In vector space form, let

- $V$ = a complex vector space of dimension $2k + 1$
- $\mathbf{Z}$ = set of 2-dimensional subspaces $W_2 \subset V$
- $\mathbf{P}^m$ = set of 1-dimensional subspaces $W_1 \subset \Lambda^2 V$
- $i$ = map taking $W_2$ to $W_1 = \Lambda^2 W_2$.

Note that we may identify

$$\check{\mathbf{P}}^m = \text{set of 1-dimensional subspaces } W_1' \subset \Lambda^2 V^*, \text{ where}$$

$$\Lambda^2 V^* = \text{space of skew-symmetric 2-forms } A : V \times V \to \mathbf{C}.$$ 

Write $[W_2] \in Z$ for the point defined by $W_2$, and $H_A \subset \mathbf{P}^m$ for the hyperplane defined by a 2-form $A$. Then it is immediate from the definitions that

$$i([W_2]) \in H_A \iff \text{res}_{W_2} A \text{ is zero}.$$ 

To determine when moreover,

$$i_*(T_{W_2}, Z) \subset T_{i(W_2), H_A},$$
let $v_1, v_2 \in W_2$ be a basis, and make a small deformation of $W_2$ by taking $v_1 + \epsilon v'_1, v_2 + \epsilon v'_2$ to be a basis of $\tilde{W}_2 \subset V \otimes \mathbb{C}[\epsilon]$. The $\tilde{W}_2$ represents a tangent vector $t$ to $Z$ at $[W_2]$ and

$$i_*(t) \subset T_{i(W_2),H_A} \iff A(v_1 + \epsilon v'_1, v_2 + \epsilon v'_2) \equiv 0 \pmod{\epsilon^2}$$

$$\iff A(v'_1, v_2) + A(v_1, v'_2) = 0,$$

Thus:

$$i_*(T_{W_2,Z}) \subset T_{i(W_2),H_A} \iff \text{for all } v'_1, v'_2, \in V,$$

$$A(v_1, v'_2) + A(v'_1, v_2) = 0$$

$$\iff W_2 \subset (\text{nullspace of } A).$$

Therefore

$$H_A \text{ is tangent to } i(Z) \iff \dim (\text{nullspace}) \geq 2.$$ 

Now the nullspace of $A$ has odd dimension, and if it is 3, one counts the dimension of the space of such $A$ as follows:

$$\dim \left( \frac{\text{space of } A \text{'s with } \dim (\text{nullspace}) = 3}{\text{dim}(\text{nullspace}) = 3} \right) = \dim \left( \frac{\text{space of } W_3 \subset V}{W_3 \subset V} \right) + \dim \Lambda^2(V/W_3)$$

$$= 3(2k - 2) + \frac{(2k - 2)(2k - 3)}{2}$$

$$= 2k^2 + k - 3.$$ 

Thus $\dim \tilde{Z} = m - 3$, and $\text{codim } \tilde{Z} = 3$! (Compare this with Buchsbaum-Eisenbud [3], where it is shown that $\tilde{Z} \subset \mathbb{P}^m$ is a “universal codimension 3 Gorenstein scheme”.)

II

The second remark concerns the Kodaira Vanishing Theorem. We want to show that Ramanujam’s strong form of Kodaira Vanishing for surfaces of Char. 0 is a consequence of a recent result of F. Bogomolov.
In particular, this is interesting because it gives a new completely algebraic proof of this result, and one which uses the Char. 0 hypothesis in a new way (it is used deep in Bogomolov’s proof, where one notes that if $V^3 \to F^2$ is a ruled 3-fold and $D \subset V^3$ is an irreducible divisor meeting the generic fibre set-theoretically in one point, then $D$ is birational to $F$). Ramanujam’s result [11] is this: let $F$ be a smooth surface of Char. 0, $D$ a divisor on $F$.

Then

$$\begin{align*}
(D^2) &> 0 \\
(D.C) &\geq 0, \quad \text{all curves } C \subset F
\end{align*}$$

$$\Rightarrow H^1(F, \mathcal{O}(-D)) = (0) \quad (1)$$

Bogomolov’s theorem is that if $F$ is a smooth surface of char. 0, $E$ a rank 2 vector bundle on $F$, then

$$C_1(E)^2 > 4C_2(E) \Rightarrow E \text{ is unstable, meaning } \exists \text{ an extension}$$

$$0 \to L(D) \to E \to I_Z L \to 0,$$  

$I_Z =$ ideal sheaf of a 0-dim. subscheme $Z \subset F$,  
$L$ invertible sheaf, $D$ a divisor  
$D \in [\text{num. pos. cone}, (D^2) > 0, (D.H) > 0]. \quad (2)$

(See Bogomolov [2], Reid [13]; another proof using reduction mod $p$ instead of invariant theory has been found by D. Gieseker.)

To prove (2) ⇒ (1), suppose $D_1$ is given satisfying the conditions of (1). Take any element $\alpha \in H^1(F, \mathcal{O}(-D_1))$ and via $\alpha$, form an extension

$$0 \to \mathcal{O}_F \xrightarrow{\mu} E \xrightarrow{\nu} \mathcal{O}_F(D_1) \to 0.$$

Note that $C_1(E) = D_1$, $C_2(E) = 0$, $(D_1^2) > 0$, so $E$ satisfies the conditions of (2). Therefore, by Bogomolov’s theorem, $E$ is unstable: this gives an exact sequence

$$0 \to L(D_2) \xrightarrow{\sigma} E \xrightarrow{\tau} I_Z L \to 0$$

$D_2 \in (\text{num. pos. cone})$. 
Note that the subsheaf \( \sigma(L(D_2)) \) of \( E \) cannot equal the subsheaf \( \mu(\mathcal{O}_F) \) in the definition of \( E \), because this would imply, comparing the 2 sequences, that \( D_2 \equiv -D_1 \) whereas both \( D_1, D_2 \) are in the numerically positive cone. Therefore, the composition

\[
L(D_2) \xrightarrow{\sigma} E \xrightarrow{\nu} \mathcal{O}_F(D_1)
\]

is not zero, hence

\[
L \cong \mathcal{O}_F(D_1 - D_2 - D_3), D_3 \text{ an effective divisor.}
\]

Next, comparing Chern classes of \( E \) in its 2 presentations, we find

\[
2C_1(L) + D_2 \equiv C_1(E) \equiv D_1 \quad \quad (3a)
\]

\[
(C_1(L) + D_2) \cdot C_1(L) + \deg Z = C_2(E) = 0. \quad \quad (3b)
\]

By \((3a)\), we find \( D_1 - D_2 - 2D_3 \equiv 0 \), hence \( L \cong \mathcal{O}_F(+D_3) \); by \((3b)\), we find \( (D_1 - D_3) \cdot D_3 \leq 0 \). But

\[
\det \begin{vmatrix} (D_1^2) & (D_1 \cdot D_3) \\ (D_1 \cdot D_3) & (D_3^2) \end{vmatrix} = (D_1^2)((D_3^2) - (D_1 \cdot D_3)) \\
+ (D_1 \cdot D_3)((D_1^2) - 2(D_1 \cdot D_3)) + (D_1 \cdot D_3)^2
\]

while

\[
(D_3^2) - (D_1 \cdot D_3) \geq 0 \quad \quad \text{by } 3b
\]

\[
(D_1^2) - 2(D_1 \cdot D_3) = (D_1 \cdot D_2) > 0 \quad \quad \text{since } D_1, D_2 \text{ num. pos.}
\]

\[
(D_1 \cdot D_3) \geq 0 \quad \quad \text{by the assumptions on } D_1.
\]

On the other hand, this det is \( \leq 0 \) by Hodge’s Index Theorem. Therefore \( (D_1 \cdot D_3) = 0 \) and det = 0. From the latter, \( D_3 \) is numerically equivalent to \( \lambda D_1, \lambda \in \mathbb{Q} \), hence \( (D_1 \cdot D_3) = \lambda(D_1^2) \). Thus \( \lambda = 0 \) and since \( D_3 \) is effective, \( D_3 = 0 \). Therefore the sub-sheaf \( \sigma(L(D_2)) \) is isomorphic to \( \mathcal{O}_F(D_1) \) and defines a splitting of the original exact sequence. Therefore the extension class \( \alpha \in H^1(\mathcal{O}_F(-D_1)) \) is 0, so \( H^1(\mathcal{O}_F(-D_1)) = 0 \).
III

The last two remarks are applications of Kodaira’s Vanishing Theorem. To me it is quite amazing how this cohomological assertion has such strong consequences, both for geometry and for local algebra. Here is a geometric application. This application is a link between the recent paper of Arakelov [1] (proving Shafarevich’s finiteness conjecture on the existence of families of curves over a fixed base curve, with prescribed degenerations), and Raynaud’s counter-example [12] to Kodaira Vanishing for smooth surfaces in char. $p$. What I claim is this (this remark has been observed by L. Szpiro also):

**Proposition.** Let $p : F \to C$ be a proper morphism of a smooth surface $F$ onto a smooth curve $C$ over a field $k$ of arbitrary characteristic. Let $E \subset F$ be a section of $p$ and assume the fibres of $p$ have positive arithmetic genus. Let $F_0$ be the normal surface obtained by blowing down all components of fibres of $p$ not meeting $E$. Then:

**Kodaira’s Vanishing Theorem** $\implies (E^2) \leq 0$. for ample divisors on $F_0$

If $\text{Char}(k) = 0$, then Kodaira’s Vanishing Theorem holds for $F_0$ (cf. [9]), so $(E^2) \leq 0$ follows. This result, and its refinement – $(E^2) < 0$ unless all the smooth fibres of $p$ are isomorphic – are due to Arakelov [1], who proved them by a very ingenious use of the Weierstrass points of the fibres $p^{-1}(x)$. On the other hand, if $\text{char}(k) = p$, Raynaud has shown how to construct examples of morphisms $p : F \to C$ and sections $E \subset F$, where all the fibres of $p$ are irreducible but singular (thus $F = F_0$), and $(E^2) > 0$. Thus Kodaira Vanishing is false for this $F$. If $\text{char}(k) = 2$ or 3, he finds in fact quasi-elliptic surfaces $F$ of this type. This Proposition is, in fact, merely an elaboration of the last part of Raynaud’s example.

**Proof of Proposition:** Suppose $(E^2) > 0$. Let $p_0 : F_0 \to C$ be the projection and let $E$ stand for the image of $E$ in $F_0$ too. Consider divisors on $F_0$ of the form

$$H = E + p_0^{-1}(U), \quad \deg U > 0.$$
Then $(H^2) > 0$ and $(H \cdot C) > 0$ for all curves $C$ on $F_0$, so $H$ is ample by the Nakai-Moisezon criterion. On the other hand, let’s calculate $H^1(F_0, \mathcal{O}(-H))$. We have

$$0 \to H^1(C, p_0, *\mathcal{O}(-H)) \to H^1(F_0, \mathcal{O}(-H)) \to H^0(C, R^1 p_0, *\mathcal{O}(-H)) \to 0.$$  

Clearly

$$p_0, *\mathcal{O}(-H) = (0) \quad \text{and} \quad R^1 p_0, *\mathcal{O}(-H) \cong (R^1 p_0, *\mathcal{O}(-E)) \otimes \mathcal{O}_C(-\mathcal{U}).$$

Now using the sequences:

$$0 \to \mathcal{O}_{F_0}(-E) \to \mathcal{O}_{F_0} \to \mathcal{O}_E \to 0$$

$$0 \to \mathcal{O}_{F_0} \to \mathcal{O}_{F_0}(E) \to \mathcal{O}_E((E^2)) \to 0$$

we find

$$\begin{array}{c}
p_0, *\mathcal{O}_{F_0} \xrightarrow{\alpha} p_0, *\mathcal{O}_E \xrightarrow{\beta} R^1 p_0, *\mathcal{O}(-E) \\
\mathcal{O}_C \quad \mathcal{O}_C
\end{array}$$

so $\alpha$ and $\beta$ are isomorphisms, and (using the fact that the genus of the fibres is positive):

$$\begin{array}{c}
0 \xrightarrow{\gamma} p_0, *\mathcal{O}_{F_0} \xrightarrow{\delta} R^1 p_0, *\mathcal{O}_E((E^2)) \\
\mathcal{O}_C \quad \mathcal{O}_C
\end{array}$$

so $\gamma$ is an isomorphism, and $\delta$ is injective. Now via the isomorphism resp: $E \to C$, let the divisor class $(E^2)$ on $E$ correspond to the divisor class $\mathcal{U}$ on $C$. Then $p_0, *\mathcal{O}_E((E^2)) \cong \mathcal{O}_C(\mathcal{U})$, and we see that

$$\mathcal{O}_C(\mathcal{U}) \subset R^1 p_0, *\mathcal{O}_{F_0} \cong R^1 p_0, *\mathcal{O}_{F_0}(-E)$$
hence
\[ \mathcal{O}_C \subset R^1 p_0, *\mathcal{O}_{F_0}(-H) \]
hence
\[ H^1(C, \mathcal{O}(-H)) \neq (0). \quad \text{Q.E.D.} \]

IV

The last remark is an application of Kodaira’s Vanishing Theorem to local algebra. It seems to me remarkable that such a global result should be useful to prove local statements about the non-existence of local rings, but this is the case. The question I want to study is that of the smoothability of non-Cohen-Macauley surface singularities. In other words, given a surface \( F, P \in F \) a non-CM-singular point, when does there exist a flat family of surfaces \( F_t \) parametrized by \( k[[t]] \) such that \( F_0 = F \) while the generic \( F_t \) is smooth. More locally, the problem is:

Given a complete non-CM-purely\[ \dagger \]2-dimensional local ring \( \mathcal{O} \) without nilpotents, when does there exist a complete 3-dimensional local ring \( \mathcal{O}' \) and a non-zero divisor \( t \in \mathcal{O}' \) such that

(a) \( \mathcal{O} \cong \mathcal{O}' / t\mathcal{O}' \)

(b) \( \mathcal{O}_P \) regular for all prime ideals \( \mathcal{P} \subset \mathcal{O} \) with \( t \notin \mathcal{P} \).

First of all, let
\[
\mathcal{O}^* = \bigoplus_{I \in \mathcal{O}} \left( \begin{array}{c}
\text{integral closure of } \mathcal{O}/I \\
\text{in its fraction field}
\end{array} \right)
\]

and let
\[
\bar{\mathcal{O}} = \left\{ a \in \mathcal{O}^* \left| \begin{array}{l}
m^n a \subset \mathcal{O} \text{ for some } n \geq 1 \\
m = \text{maximal ideal in } \mathcal{O}
\end{array} \right. \right\}
\]

\[ \dagger \text{i.e. } \mathcal{O}/I \text{ is 2-dimensional for all minimal prime ideals of } \mathcal{I} \subset \mathcal{O}. \]
= \Gamma(\text{Spec } \mathcal{O} \text{ – closed pt., } \mathcal{O})

Note that \( \widetilde{\mathcal{O}} \) is a finite \( \mathcal{O} \)-module and \( m^n \cdot \widetilde{\mathcal{O}} \subset \mathcal{O} \) for some large \( n \), so that \( \mathcal{O}/\mathcal{O} \) is an \( \mathcal{O} \)-module of finite length. Moreover, it is easy to see that \( \widetilde{\mathcal{O}} \) is a semi-local Cohen-Macaulay ring. It has been proven by Rim [14] (cf. also Hartshorne [6], Theorem 2.1, for another proof) that:

\( \mathcal{O} \text{ smoothable } \Rightarrow \widetilde{\mathcal{O}} \text{ local.} \)

The result we want to prove is:

**Theorem.** Assume \( \text{char}(\mathcal{O}/m) = 0 \), \( \text{Spec } \mathcal{O} \) has an isolated singularity at its closed point and that \( \mathcal{O} \) is smoothable, so that, by the remarks above, \( \widetilde{\mathcal{O}} \) is a normal local ring. Let \( \pi : X^* \to \text{Spec } \mathcal{O} \) be a resolution and let

\[ p_a(\widetilde{\mathcal{O}}) = l(R^1\pi_*\mathcal{O}_X) \]

be the genus of the singularity \( \widetilde{\mathcal{O}} \). Then

\[ l(\mathcal{O}/\mathcal{O}) \leq p_a(\widetilde{\mathcal{O}}). \]

Actually, for our applications, we want to know this result for rings \( \mathcal{O} \) where \( \text{Spec } \mathcal{O} \) has ordinary double curves too, with a suitable definition of \( p_a \). We will treat this rather technical generalization in an appendix.

For example, the theorem shows:

**Corollary.** Let \( \widetilde{\mathcal{O}} = k[[x, y]] \), \( \text{char } k = 0 \). Let \( I \not\subset (x, y) \) be an ideal of finite codimension. Then if \( \mathcal{O} = k + I \), \( \mathcal{O} \) is not smoothable.

On the other hand, if \( F \subset \mathbb{P}^n \) is an elliptic ruled surface and \( \mathcal{O}' \) is the completion of the local ring of the cone over \( F \) at its apex, then \( \mathcal{O}' \) is a normal 3-dimensional ring which is not Cohen-Macaulay. If \( C = V(t) = (F \cdot \mathbb{P}^{n-1}) \) is a generic hyperplane section of \( F \), then \( t \in \mathcal{O}' \) and \( \mathcal{O} = \mathcal{O}'/t\mathcal{O}' \) is the completion of the local ring of the cone over \( C \) at its apex. Now \( C \) is an elliptic curve, but embedded by an incomplete
linear system – in fact, \( C \) is a projection of an elliptic curve \( \widetilde{C} \) in \( \mathbb{P}^n \) from a point not on \( \widetilde{C} \) – this follows from the exact sequence:

\[
0 \to H^0(\mathcal{O}_F) \to H^0(\mathcal{O}_F(1)) \to H^0(\mathcal{O}_C(1)) \to H^1(\mathcal{O}_F) \to 0
\]

Let \( \widetilde{\mathcal{O}} \) be the completion of the local ring of the cone over \( \widetilde{C} \) at its apex. Then \( \widetilde{\mathcal{O}} \) is a normal 2-dimensional ring, in fact an “elliptic singularity”, i.e., \( p_a(\widetilde{\mathcal{O}}) = 1 \); moreover \( \widetilde{\mathcal{O}} \supset \mathcal{O} \) and \( \dim \widetilde{\mathcal{O}} / \mathcal{O} = 1 \). This shows that there are smoothable singularities \( \mathcal{O} \) with

\[
l(\widetilde{\mathcal{O}} / \mathcal{O}) = p_a(\widetilde{\mathcal{O}}) = 1.
\]

**Proof of Theorem.** Let \( \mathcal{O} \cong \mathcal{O}' / t\mathcal{O}' \) give the smoothing of \( \mathcal{O} \). The proof is based on an examination of the exact sequence of local cohomology groups:

\[
(*) \ldots \to H^1_{\{x\}}(\mathcal{O}') \to H^1_{\{x\}}(\mathcal{O}) \to H^2_{\{x\}}(\mathcal{O}') \xrightarrow{\alpha} H^2_{\{x\}}(\mathcal{O}) \to \ldots
\]

where \( x \in \text{Spec} \mathcal{O} \subset \text{Spec} \mathcal{O}' \) represents the closed point.

What can we say about each of these groups?

(a) \( H^1_{\{x\}}(\mathcal{O}') \) is zero since \( \mathcal{O}' \) is an integrally closed ring of dimension 3, hence has depth at least 2.

(b) To compute \( H^1_{\{x\}}(\mathcal{O}) \), use

\[
H^0(\text{Spec} \mathcal{O}, \mathcal{O}) \to H^0(\text{Spec} \mathcal{O} - \{x\}, \mathcal{O}) \to H^1_{\{x\}}(\mathcal{O}) \to 0
\]

which gives us:

\[
H^1_{\{x\}}(\mathcal{O}) \cong \widetilde{\mathcal{O}} / \mathcal{O}.
\]

(c) As for \( H^2_{\{x\}}(\mathcal{O}') \), it measures the degree to which \( \mathcal{O}' \) is not Cohen-Macauley. A fundamental fact is that it is of finite length—cf. Theoreme de finitude, p. 89, in Grothendieck’s seminar [15].
(d) As for \(H^2_{\{x\}}(\mathcal{O})\), we can say at least:

\[
H^2_{\{x\}}(\mathcal{O}) \cong H^1(\text{Spec } \mathcal{O} - \{x\}, \mathcal{O}) \\
\cong H^1(\text{Spec } \widetilde{\mathcal{O}} - \{x\}, \widetilde{\mathcal{O}}) \\
\cong H^2_{\{x\}}(\widetilde{\mathcal{O}})
\]

but unfortunately this group is huge: it is not even an \(\widetilde{\mathcal{O}}\)-module of finite type.

However, for any local ring \(\mathcal{O}\) with residue characteristic \(O\) and with isolated singularity, we can define, by using a resolution of \(\text{Spec } \mathcal{O}\), important subgroups:

\[
H^i_{\{x\},\text{int}}(\mathcal{O}).
\]

Namely, let \(\pi : X \to \text{Spec } \mathcal{O}\) be a resolution and set

\[
H^i_{\{x\},\text{int}}(\mathcal{O}) = \text{Ker}[\pi^* : H^i_{\{x\}}(\mathcal{O}) \to H^i_{\pi^{-1}(x)}(\mathcal{O}_X)].
\]

This is independent of the resolution, as one sees by comparing any 2 resolutions \(\pi_i : X_i \to \text{Spec } \mathcal{O}\), \(i = 1, 2\), via a 3rd:

\[
\begin{array}{ccc}
X_1 & \xrightarrow{f} & X_3 \\
\pi_3 & \swarrow & \searrow \\
X_3 & \xrightarrow{\pi_1} & \text{Spec } \mathcal{O} \\
\pi_1 & \swarrow & \searrow \\
X_2 & \xrightarrow{\pi_2} & X_3 \\
\end{array}
\]

and using the Leray spectral sequence

\[
H^p_{\pi_1^{-1}(x)}(X_1, R^qf_* (\mathcal{O}_{X_3})) \Rightarrow H^*_\pi(x_3, \mathcal{O}_{X_3})
\]

plus Matsumura’s result \(R^qf_*(\mathcal{O}_{X_3}) = (0), q > 0\) where \(X_1\) and \(X_3\) are smooth and characteristic zero. Moreover, when \(\mathcal{O} \cong \mathcal{O}'/I\), then the restriction map

\[
H^i_{\{x\}}(\mathcal{O}') \to H^i_{\{x\}}(\mathcal{O})
\]
gives
\[ H^i_{\{x\},\text{int}}(\mathcal{O}') \to H^i_{\{x\},\text{int}}(\mathcal{O}) \]
because we can find resolutions fitting into a diagram:

\[ \begin{array}{c}
X \\
\downarrow \quad \downarrow \\
\text{Spec } \mathcal{O} \quad \text{Spec } \mathcal{O}'.
\end{array} \]

Next, we prove using the Kodaira Vanishing Theorem and following Hartshorne and Ogus ([16] p. 424):

**Lemma.** Assume \( x \) is the only singularity of \( \mathcal{O} \), \( \dim \mathcal{O} = n \) and \( \pi : X \to \text{Spec } \mathcal{O} \) is a resolution. Then

\[ H^i_{\{x\}',\text{int}}(\mathcal{O}) \cong H^i_{\{x\}}(\mathcal{O}), \quad 0 \leq i \leq n - 1 \]

and

\[ H^i_{\{x\}',\text{int}}(\mathcal{O}) \cong R^{i-1}\pi_*(\mathcal{O}_X)_x, \quad 2 \leq i \leq n. \]

**Proof.** Because \( \mathcal{O} \) has an isolated singularity, we may assume \( \mathcal{O} \cong \mathcal{O}_{x,X_0} \), where \( X_0 \) is an \( n \)-dimensional projective variety with \( x \) its only singular point. We may assume our resolution is global:

\[ \pi : X \to X_0. \]

Let \( \tilde{X} = X \times_{X_0} \text{Spec } \mathcal{O} \) and let \( I \) be the injective hull of \( \mathcal{O}_{x,X_0}/m_{x,X_0} \) as \( \mathcal{O}_{x,X_0} \)-module. Then according to Hartshorne’s formal duality theorem (cf. [7] p. 94), for all coherent sheaves \( \mathcal{F} \) on \( X \), the 2 \( \mathcal{O} \)-modules

\[ H^i_{\pi-1,x}(\mathcal{F}), \quad \text{Ext}^{n-i}_{\mathcal{O}_{\tilde{X}}}(\mathcal{F}, \Omega^n_{\tilde{X}}) \]

are dual via Hom(\( - , I \)). In particular,

\[ H^i_{\pi-1,x}(\mathcal{O}_X), \quad H^{n-i}(\Omega^n_{\tilde{X}}) \]
are dual. But

\[ H^{n-i}(\Omega^n_X) \cong R^{n-i} \pi_* (\Omega^n_X) \otimes \mathcal{O}_{X_0} \mathcal{O} \]

and it has been shown by Grauert and Riemenschneider [5] that \( R^i \pi_* (\Omega^n_X) = (0), \ i > 0 \). (This is a simple consequence of Kodaira’s Vanishing Theorem because if \( L_0 \) is an ample invertible sheaf on \( X_0 \) with \( H^i(X_0, L_0 \otimes \pi_* \Omega^n_X) = (0), \ i > 0 \), then by the Leray Spectral Sequence:

\[
\begin{align*}
H^i(X, \pi^* L_0 \otimes \Omega^n_X) &\cong H^0(X_0, L_0 \otimes R^i \pi_* \Omega^n_X) \\
H^{n-i}(X, (\pi^* L_0)^{-1}) &\text{dual}
\end{align*}
\]

and Kodaira’s Vanishing Theorem applies to all invertible sheaves \( M \) such that \( \Gamma(X, M^n) \) is base point free and defines a birational morphism, \( n \geq 0 \) (cf. [9]).) Recapitulating, this shows \( H^{n-i}(\Omega^n_X) = (0), \ i < n \), hence \( H^i_{\pi^{-1}_x}(\mathcal{O}_X) = (0), \ i < n \), hence \( H^i_{\pi^{-1}_x}(\mathcal{O}_X) \cong H^i_{\pi^{-1}_x}(\mathcal{O}_X) \) is an isomorphism.

To get the second set of isomorphisms, we use the Leray Spectral Sequence:

\[
H^0_{\pi^{-1}_x}(X_0, R^q \pi_* \mathcal{O}_X) \Rightarrow H^*_\pi_{\pi^{-1}_x}(X, \mathcal{O}_X).
\]

The only non-zero terms occur for \( p = 0 \) or \( q = 0 \), so we get a long exact sequence

\[
\ldots \to H^0_{\pi^{-1}_x}(R^{i-1} \pi_* \mathcal{O}_X) \to H^i_{\pi^{-1}_x}(\pi_* \mathcal{O}_X) \to H^i_{\pi^{-1}_x}(\mathcal{O}_X) \to H^0_{\pi^{-1}_x}(R^i \pi_* \mathcal{O}_X) \\
\quad \to H^{i+1}_{\pi^{-1}_x}(\pi_* \mathcal{O}_X) \to \ldots
\]

Using the first part, plus the isomorphism:

\[
H^i_{\pi^{-1}_x}(\pi_* \mathcal{O}_X) \cong H^{i-1}(\text{Spec } \mathcal{O} - \{x\}, \pi_* \mathcal{O}_X)
\cong H^{i-1}(\text{Spec } \mathcal{O} - \{x\}, \mathcal{O})
\cong H^i_{\pi^{-1}_x}(\mathcal{O}), \ i \geq 2,
\]

we get the results. Q.E.D. □
We now go back to the sequence (\(\ast\)). It gives us:

\[
0 \rightarrow \mathcal{O}/\mathcal{O} \rightarrow H^2_{\{x\},\text{int}}(\mathcal{O}') \xrightarrow{t} H^2_{\{x\},\text{int}}(\mathcal{O}') \rightarrow R^1\pi_*((\mathcal{O}_X)_x) \rightarrow \ldots
\]

where \(\pi : X \rightarrow \text{Spec} \, \mathcal{O}\) is a resolution. Therefore

\[
l(\mathcal{O}/\mathcal{O}) = l(\ker \text{ of } t \text{ in } H^2_{\{x\},\text{int}}(\mathcal{O}')) \\
= l(\text{Coker } \text{ of } t \text{ in } H^2_{\{x\},\text{int}}(\mathcal{O}')) \\
\leq l(R^1\pi_*((\mathcal{O}_X)_x)) = p_a(\mathcal{O}). \quad \text{Q.E.D.}
\]

**Appendix**

The purpose of this appendix is to make a rather technical extension of the result in § IV, which seems to be better for use in applications. Let \(X\) be an affine surface, reduced, with at most ordinary double curves, plus one point \(P \in X\) about which we know nothing. Let

\[
\widetilde{X} = \text{Spec } \Gamma(X - P, \mathcal{O}_X)
\]

so that we get

\[
\pi_1 : \widetilde{X} \rightarrow X,
\]

an isomorphism outside \(P\), everywhere a finite morphism, with \(\widetilde{X}\) Cohen-Macauley. Our goal is to show that in certain cases \(X\) is not smoothable near \(P\), i.e., \(\not\exists\) an analytic family

\[
f : X' \rightarrow \Delta = \text{disc in the } t\text{-plane},
\]

where \(f^{-1}(0) \approx (\text{neighborhood of } P \text{ in } X)\), and \(f^{-1}(t)\) is smooth, \(t \neq 0\). (Here we work in the analytic setting rather than the formal one to be able below to take an exponential.) We know that a necessary condition for \(X'\) to exist is that \(\pi_1^{-1}(P)\) is one point \(\widetilde{P}\), so henceforth we assume this too. Next blow up \(\widetilde{X}\), but only at \(\widetilde{P}\) and at centers lying over \(\widetilde{P}\): it is not hard to see that we arrive in this way at a birational proper morphism

\[
\pi_2 : X^* \rightarrow \widetilde{X}
\]
such that $X^*$ has at most ordinary double curves and pinch points (points like $z^2 = x^2y$), these pinch points moreover lying over $\tilde{P}$. Define

$$p_a(\mathcal{O}_{\tilde{P}}) = \dim_{\mathcal{C}}[R^1\pi_{2,*}(\mathcal{O}_{X^*})_{\tilde{P}}].$$

It is easy to verify that this number is independent of the choice of $X^*$. (However, this would not be true if $\tilde{X}$ had cuspidal lines—in this case, there is no bound on $\dim R^1\pi_*$ as you blow up $\tilde{X}$ more and more!) We claim the following

261 Theorem. If $X$ is smoothable near $P$, then $l(\mathcal{O}_{\tilde{P}}/\mathcal{O}_P) \leq p_a(\mathcal{O}_{\tilde{P}})$.

Proof. We follow the same plan as in the case where $\mathcal{O}$ has an isolated singularity, except that, for an arbitrary local ring $\mathcal{O}$, we set

$$H^i_{\{x\}, \text{int}}(\mathcal{O}) = \bigcup_{\text{modifications } \pi : X \to \text{Spec } \mathcal{O} \text{ where } X - \pi^{-1}(x) \to \text{Spec } \mathcal{O} - \{x\}} [\ker : H^i_{\{x\}}(\mathcal{O}) \to H^i_{\pi^{-1}(x)}(\mathcal{O}_X)].$$

The proof is then the same as before except that we cite only the following case of the lemma:

Theorem (Boutot [17]). Let $\mathcal{O}$ be a normal excellent local $k$-algebra, with residue field $k$, and $\text{char}(k) = 0$. Then:

$$H^2_{\{x\}, \text{int}}(\mathcal{O}) = H^2_{\{x\}}(\mathcal{O}).$$

This result is a Corollary of Proposition 2.6, Chapter V [17]. Since $\text{char}(k) = 0$, we may disregard “red” in that Proposition and apply it to the values of the functor on the dual numbers. It tells us that there is a blow-up $\pi : X \to \text{Spec}(\mathcal{O})$ concentrated at the origin such that

$$\text{Pic}_{X/k}(k[\epsilon]/(\epsilon^2)) \to \text{Pic}_{\text{Spec}(\mathcal{O}) - \{x\}}(k[\epsilon]/(\epsilon^2))$$

is an isomorphism. In other words, in the sequence:

$$\to H^1(X, \mathcal{O}_X) \xrightarrow{\alpha} H^1(X - \pi^{-1}(x), \mathcal{O}_X) \xrightarrow{\beta} H^2_{\pi^{-1}(x)}(\mathcal{O}_X) \to$$

$\alpha$ is surjective, hence $\beta$ is zero.

Singular Modular Forms of Degree $s$

By S. Raghavan

1. For a natural number $s$, let $H_s$ denote the Siegel half-plane of degree $s$, namely the space of $s$-rowed complex symmetric matrices $W = U + iV$ with $U$, $V$ real and $V$ positive-definite. The Siegel modular group $\Gamma_s = \text{Sp}(s, \mathbb{Z}) = \{ M = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \mid A, B, C, D \text{ } s\text{-rowed integral square matrices with } M(M^{-1}E_s^{-1}M') = \begin{pmatrix} 0 & E_s \\ -E_s & 0 \end{pmatrix} \}$ acts on $H_s$ as a discontinuous group of analytic homeomorphisms $W \mapsto M(W) = (AW + B)(CW + D)^{-1}$ of $H_s$ (called modular transformations of degree $s$). By a modular form of degree $s$ and weight $k (\geq 0)$ we mean a complex-valued function $f$ holomorphic in the $s(s + 1)/2$ independent elements of $W$ such that $f(M(W)) \det(CW + D)^{-k} = f(W)$ for every $M = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in \Gamma_s$ and further, for $s = 1$, $f$ is bounded in a fundamental domain for $\Gamma_s$ in $H_s$ [6]. Let $\{\Gamma_s, k\}$ denote the complex vector space of such modular forms. Every $f \in \{\Gamma_s, k\}$ has the Fourier expansion

$$f(W) = \sum_N a(N) \exp(\pi i \text{ tr } (NW))$$

where $\text{tr}$ denotes the trace and $N$ runs over all $s$-rowed integral non-negative definite matrices with even diagonal elements. If $a(N) = 0$ for every positive definite $N$, we call $f$ a singular modular form. On the other hand, if $a(N) = 0$ for all $N$ which are not positive-definite, $f$ is known as a cusp form. It is immediate that
the only cusp form which is, at the same time, a singular modular form is the constant 0. Writing $W$ in $H_s$ as $\left( \frac{Z}{w} \right)$ with $z \in H_1$, $Z \in H_{s-1}$, we know $g = \Phi(f)$ given by $g(Z) = \lim_{\lambda \to \infty} f \left( \left( \begin{array}{cc} 0 & i \lambda \\ i \lambda & 0 \end{array} \right) \right)$ is in $\{ \Gamma_{s-1}, k \}$. This map $\Phi : \{ \Gamma_s, k \} \to \{ \Gamma_{s-1}, k \}$ (with $\{ \Gamma_0, k \} = \mathbb{C}$, by convention) is known as the Siegel operator and its kernel consists precisely of cusp forms in $\{ \Gamma_s, k \}$.

It is clear that $\{ \Gamma_s, k \}$ contains no singular modular form $\neq 0$, if and only if every $f$ in $\{ \Gamma_s, k \}$ is uniquely determined by the set of its Fourier coefficients $\{ a(N) | N \text{ positive definite} \}$ referring to (1).

For $s = 1$, a singular modular form is necessarily a constant. For $s > 1$, we know from Resnikoff ([3], [4]) that singular modular forms can exist only for $k$ of the form $r/2$ with $r$ integral and $0 \leq r < s$; such weights, for given $s$, are called singular weights.

Even for $s > 1$, it turns out, as we shall see in a while, that singular modular forms are particularly simple in their structure; in fact, they are quite arithmetical in nature in as much as they are just linear combinations of theta series associated with “positive-definite even quadratic forms of determinant 1 in $r$ variables” (and with $W \in H_s$). It is well known that such quadratic forms exist only when $r$ is a multiple of 8.

2. Let $S$ be an $r$-rowed integral positive-definite matrix. Then associated to $S$ and $W \in H_s$, we define the theta series

$$t(W; S) = \sum_G \exp(\pi i \text{tr} (G' S G W))$$

where the summation is over all integral matrices $G$ of $r$ rows and $s$ columns. The series represents a holomorphic function of $W$ on $H_s$. From Witt [7], we know that it is a modular form of degree $s$ and weight $r/2$, if $S$ is positive-definite, integral with diagonal elements even and of determinant 1; as already mentioned, 8 has to divide $r$ in this case. Thus, for $s > r$, $t(W; S)$ is always a singular modular form for such $S$, since, in the expansion (1) for $t(W; S)$ only $N$ of the form $G' S G$ with integral $G$ of
Singular Modular Forms of Degree $s$

$r(< s)$ rows and $s$ columns can occur. From the analytic theory of quadratic forms \([5]\), we know that, for given $r$ divisible by 8, all such even positive-definite $S$ of determinant 1 constitute a single “genus” consisting of finitely many $\mathbb{Z}$-equivalence classes (Two $r$-rowed matrices $A$, $B$ are said to be $\mathbb{Z}$-equivalent, if there exists an integral matrix $U$ of determinant $\pm 1$ such that $U'AU = B$). Let $S_1, \ldots, S_h$ form a complete set of representatives of these classes. Then $t(W; S_i)$ depends only on the class of $S_i$ for $1 \leq i \leq h$. We claim that $t(W; S_i), 1 \leq i \leq h$ are linearly independent over the field of complex numbers for $W \in H_r$. In fact, the Fourier coefficient of $t(W; S_i)$ corresponding to $S_j$ (in place of $N$) as in (1) is given by $\delta_{ij}E(S_j)$ where $\delta_{ij}$ is the Kronecker delta and $E(S_j)$ is the number of integral matrices $U$ with $U'S_jU = S_j$. Any linear relation of the form $\sum_{1 \leq i \leq h} b_i t(W; S_i) = 0$ with $b_i$ not all zero, immediately implies that $b_i E(S_i) = 0$ for every $i$ and yields a contradiction, since we have $E(S_i) \geq 2$, always. It is immediately seen, by applying the $\Phi$-operator, that for $s \geq r$ and $W \in H_s$, $t(W, S_1), \ldots, t(W, S_h)$ are linearly independent.

**Theorem.** Every (singular) modular form of degree $s$ and weight $r/2$ with $r$ integral and $0 < r < s$ vanishes identically unless $r$ is a multiple of 8. If 8 divides $r$, every modular form of degree $s$ and weight $r/2$ is a linear combination of the theta series $t(W; S_i), 1 \leq i \leq h$, where $W \in H_s$ and $S_1, \ldots, S_h$ are representatives of $\mathbb{Z}$-equivalence classes of $r$-rowed positive-definite integral matrices with even diagonal elements and determinant 1.

**Remark.** The theorem does not say anything about the nature of $\{\Gamma_r, r/2\}$ for $r$ divisible by 8. If the Siegel operator from $\{\Gamma_{r+1}, r/2\}$ to $\{\Gamma_r, r/2\}$ were onto, then one can conclude that $\{\Gamma_r, r/2\}$ is generated over $\mathbb{C}$ by theta series. If $r = 8$, we know from (1), (2) that $\{\Gamma_s, 4\}$ has dimension 1 over $\mathbb{C}$ for $s \leq 4$. It has been conjectured by Freitag that even for $5 \leq s \leq 8$, $\{\Gamma_s, 4\}$ has dimension 1, being generated by a theta series.

Assume that the theorem has been proved for $s = r + 1$. We
then claim that it is valid for \( s > r + 1 \). First, for \( r \) not divisible by 8, if \( \{ \Gamma_{r+1}, r/2 \} \) consists only of 0, then the Siegel operator \( \Phi \) from \( \{ \Gamma_{r+2}, r/2 \} \) is clearly onto \( \{ \Gamma_{r+1}, r/2 \} = \{ 0 \} \) and its kernel is already \( \{ 0 \} \) since every cusp form which is a singular form vanishes identically. Thus, for \( r \) not divisible by 8, \( \{ \Gamma_{r+2}, r/2 \} = \{ 0 \} \) and a similar argument gives \( \{ \Gamma_s, r/2 \} = \{ 0 \} \) for \( s \geq r + 2 \). On the other hand, let, for \( r \) divisible by 8, \( \{ \Gamma_{r+1}, r/2 \} \) be a linear combination of theta series \( t(W; S_i), 1 \leq i \leq h \) with \( W \in H_{r+1} \). If \( W^* = (W^*_{\ast\ast}) \in H_{r+2} \), clearly \( \Phi(t(W^*; S_i)) = t(W; S_i) \), i.e. the Siegel operator from \( \{ \Gamma_{r+2}, r/2 \} \) is onto. Again by the same argument as above, \( \Phi \) is an isomorphism, implying that \( \{ \Gamma_{r+2}, r/2 \} \) is generated by theta series for \( r \) divisible by 8; the spaces \( \{ \Gamma_s, r/2 \} \) for \( s > r + 2 \) are taken care of in a similar manner.

Therefore, we proceed to prove the theorem for \( s = r + 1 \). Let \( \{ \Gamma_{r+1}, r/2 \} \) contain an \( f \neq 0 \). For \( W = \left( \begin{array}{c} Z \\ w' \\ z \end{array} \right) \in H_{r+1} \) with \( z \in H_1 \), \( Z \in H_r \), let us write (1) as

\[
f(W) = \sum_N a(N) \exp(\pi i (mz + 2n'w + tr(TZ)))
\]

where \( N \) runs over all matrices of the form \( \left( \begin{array}{ccc} T & n \\ n' & m \end{array} \right) \) which are non-negative definite, \( (r + 1) \)-rowed, integral with even diagonal elements, \( T \) being \( r \)-rowed. Further, \( f \) being a singular modular form, \( a(N) = 0 \) for \( \det N > 0 \). If \( \det T > 0 \), we can write \( N \) above as

\[
N = \left( \begin{array}{cc} T & 0 \\ 0' & m - T^{-1}[n] \end{array} \right) \left[ E_r \ T^{-1} \right].
\]

Here \( E_r \) denotes the \( r \)-rowed identity matrix and for two matrices \( A, B \) we abbreviate \( B'AB \) (when defined) as \( A[B] \). Thus, for \( \det T > 0 \), we have necessarily \( m = T^{-1}[n] \).

For integral \( A \) with \( \det A = 1 \), we have \( f(W[A]) = f(W) \). This gives \( a(N) = a(N[A]) \). In particular, for integral \( r \)-rowed columns \( g \) and

\[
N = \left( \begin{array}{cc} T & n \\ n' & T^{-1}[n] \end{array} \right), \quad N_1 = \left( \begin{array}{cc} T & T_g + n \\ (T_g + n)' & T^{-1}[T_g + n] \end{array} \right) = N \left[ E_r \ g \right] \begin{array}{c} 0' \\ 1 \end{array}
\]
the corresponding coefficients \(a(N)\) and \(a(N_1)\) coincide.

For positive \(T\) as above and an integral \(r\)-rowed column \(l\) with \(T^{-1}[l]\) even, let \(b(T; l) = a\left(\begin{bmatrix} T & T^{-1}[l] \end{bmatrix}\right)\) and let \(b(T; l) = 0\) otherwise. Then \(b(T; Tg + l) = b(T; l)\) for every integral \(g\). Let \(l\) run over a complete set of \(r\)-rowed integral columns such that no two distinct columns say \(l_1, l_2\) satisfy \(l_1 = l_2 + Tg\) for some integral column \(g\) (We write \(l \mod T\), in symbols). We can write

\[
f(W) = \sum_{T > 0} \exp(\pi i \text{tr}(TZ)) \sum_{l \mod T} b(T; l) \sum_g \exp(\pi iz^{-1}[Tg + l]) + 2\pi i (Tg + l)'w + \sum_{T_1 \geq 0, \det T_1 = 0} h(z, w; T_1) \exp(\pi i \text{tr}(T_1 Z))
\]

where \(T, T_1\) respectively run over positive-definite and singular non-negative-definite \(r\)-rowed integral matrices with even diagonal elements and \(g\) runs over all \(r\)-rowed integral columns. Let us abbreviate the innermost sum in the first term on the right side of (3) as \(\vartheta(z, w; T, l)\). It is easy to see that

\[
\begin{pmatrix} Z & w \\ w' & z \end{pmatrix} = W \mapsto W_1 = \begin{pmatrix} Z - z^{-1}ww' & z^{-1}w' \\ z^{-1}w' & -z^{-1} \end{pmatrix} = \begin{bmatrix} E_r & 0 & 0 & 0 \\ 0' & 0 & 0' & -1 \\ 0 & 0 & E_r & 0 \\ 0' & 1 & 0' & 0 \end{bmatrix} \langle W \rangle
\]

is a modular transformation of degree \(s\). Now, since \(f \in \{\Gamma_s, r/2\}\), we have

\[
f(W_1)z^{-r/2} = f(W)
\]

taking that branch of \(z^{-r/2}\) assuming the value \(\exp(-\pi ir/4)\) corresponding to the point \(iE_{r+1}\). On the other hand, it is easy to check that, for positive-definite \(T\),

\[
\vartheta(-z^{-1}, z^{-1}w; T, l) = \exp(\pi iz^{-1}T[w]) \times 
\]
\[
\times \sum_{g \text{ integral}} \exp(-\pi i T[g + T^{-1}l - w]z^{-1})
= \exp(\pi iz^{-1}T[w])(\det(iz^{-1}T))^{-1/2} \times \\
\sum_{g \text{ integral}} \exp(\pi iz T^{-1}[g] + 2\pi i g'(T^{-1}l - w))
\]

using the theta transformation formula. Let us write \(T^{-1}g\) again as \(T^{-1}(j + p)\) where \(j\) runs modulo \(T\) and \(p\) runs over all integral columns as \(g\) does so. Then we have

\[
\vartheta(-z^{-1}, z^{-1}w; T, l) = (i/z)^{-r/2}(\det T)^{-1/2} \exp(\pi iz^{-1}T[w]) \times \\
\sum_{j \mod T} \sum_{p \text{ integral}} \exp(\pi i T[p + T^{-1}j]z+ \\
+ 2\pi i l'(T^{-1}j + p) - 2\pi i(Tp + j)'w) \\
= (i/z)^{-r/2}(\det T)^{-1/2} \exp(\pi iz^{-1}T[w]) \times \\
\sum_{j \mod T} \exp(-2\pi i l'T^{-1}j)\vartheta(z, w; T, j)
\]

(4)

noting that \(\exp(2\pi i l'p) = 1\) and making the change \(p \to -p\) and \(j \to -j\). From (2), (3) and (4), we obtain

\[
\sum_{T, l \mod T} b(T; l) \vartheta(z, w; T, l) \exp(\pi i tr(TZ)) \\
+ \sum_{T, l \mod T} h(z, w; T_1) \times \exp(\pi i tr(T_1Z)) \\
= \sum_{T, l \mod T} b(T; l) \exp(\pi i tr(TZ) - \pi iz^{-1}T[w]) \\
\times \vartheta(-z^{-1}, z^{-1}w; T, l) + \\
\sum_{T_1} h(-z^{-1}, z^{-1}w; T_1) \exp(\pi i tr(T_1Z) - \pi iz^{-1}T_1[w]) \\
= (i/z)^{-r/2} \sum_{T, l \mod T} b(T; l)(\det T)^{-1/2} \exp(\pi i tr(TZ)) \times
\]
\[
\sum_{j \mod T} \exp(-2\pi i j'T^{-1}l)\vartheta(z, w; T, j) + \\
\sum_{T_1} h(-z^{-1}, z^{-1}w; T_1) \exp(-\pi i z^{-1}T_1[w]) \exp(\pi i \text{tr}(T_1 Z))
\]

\[
= (i/z)^{-r/2} \sum_{0<T,j \mod T} (\det T)^{-1/2} \sum_{l \mod T} b(T; l) \exp(-2\pi i j'T^{-1}l) \times \\
\exp(\pi i \text{tr}(TZ)) \vartheta(z, w; T, j) + \\
\sum_{T_1} h(-z^{-1}, z^{-1}w; T_1) \exp(-\pi i z^{-1}T_1[w]) \exp(\pi i \text{tr}(T_1 Z)).
\]

Comparing the coefficient of \(\exp(\pi i \text{tr}(TZ))\) for fixed positive-definite \(T\) on both sides, we get

\[
z^{r/2} \sum_{j \mod T} b(T; j) \vartheta(z; w; T, j) = (i/z)^{-r/2} (\det T)^{-1/2} \times \\
\sum_{j \mod T} \vartheta(z; w; T, j) \sum_{l \mod T} b(T : l) \exp(-2\pi i j'T^{-1}l).
\]

This implies, in turn, that

\[
b(T : j) = \exp(-\pi ir/4)(\det T)^{-1/2} \sum_{l \mod T} b(T; l) \exp(-2\pi il'T^{-1}j).
\]

In particular, we have for \(T\) with \(\det T > 0\),

\[
a \begin{pmatrix} T & 0 \\ 0' & 0 \end{pmatrix} = (\det T)^{-1/2} \exp(-\pi i r/4) \sum_{l \mod T} a \begin{pmatrix} T & l \\ l' & T^{-1}[l] \end{pmatrix}.
\]

(cf. [1](13), p. 284, [4] §§ 5-6). Note that \((\det T)^{1/2}\) is the positive square root.

For given positive-definite \(T\) and \(l \mod T\) as above, there exists an integral matrix \(A\) of determinant 1 such that

\[
\begin{pmatrix} T & l \\ l' & T^{-1}[l] \end{pmatrix} = A' \begin{pmatrix} T_0 & 0 \\ 0' & 0 \end{pmatrix} A.
\]

Since the left hand side is integral with even diagonal elements and of rank \(r\), the same is true of \(T_0\). If \(A = \begin{pmatrix} d & e \\ b & a \end{pmatrix}\) with \(r\)-rowed
square $d$, we have $T = T_0[d]$ implying that $d$ is nonsingular. Further $l = d'T_0c$. If $\det d = \pm 1$, then $l = d'T_0d$. $d^{-1}c = Td^{-1}c$ ($\equiv 0 \mod T$, in the sense that $l = Tg$ for an integral column $g$).

Thus, if there exists an integral $l$ not of the form $Tg$ for an integral $g$ such that $T^{-1}[l]$ is even, then necessarily $\det d$ has absolute value at least equal to 2. On the other hand, there always exists an integral $l$ such that $T^{-1}[l]$ is an even integer.

Let us call $T$ imprimitive if there exists an integral matrix $d$ with $\det d \neq 0, \pm 1$, such that $T[d^{-1}]$ is integral with even diagonal elements. If $T$ is not imprimitive, we call $T$ primitive.

For primitive $T$, the only term occurring on the right side of (4) corresponds to $l = 0$ (i.e. $l \equiv 0(\mod T)$). In this case then, we have

$$\left(1 - \frac{\exp(-\pi ir/4)}{(\det T)^{1/2}}\right) a \left(\begin{pmatrix} T & 0 \\ 0' & 0 \end{pmatrix}\right) = 0. \quad (7)$$

Unless

$$\det T = 1 \quad \text{and} \quad r \equiv 0(\mod 8), \quad (8)$$

(7) implies that $a \left(\begin{pmatrix} T & 0 \\ 0' & 0 \end{pmatrix}\right) = 0$. We may rewrite (4) as

$$a \left(\begin{pmatrix} T & 0 \\ 0' & 0 \end{pmatrix}\right) = \frac{\exp(-\pi ir/4)}{(\det T)^{1/2}} \sum_{(d,c)} a \left(\begin{pmatrix} T[d^{-1}] & 0 \\ 0' & 0 \end{pmatrix}\right) \quad (5')$$

where, on the right hand side, the summation is over integral matrices $(d,c)$ of $r$ rows and $r + 1$ columns having discriminant 1, with integral non-singular $d$ not mutually differing by a left sided integral matrix factor of determinant $\pm 1$ and with $c$ running only modulo $d$. From (5') and (8), we conclude that

$$"a \left(\begin{pmatrix} T & 0 \\ 0' & 0 \end{pmatrix}\right) \neq 0, \ \det T > 1" \Rightarrow T \quad \text{is imprimitive.} \quad (9)$$

On the other hand, if there exists $T$ as above with $\det T = 1$ and $a \left(\begin{pmatrix} T & 0 \\ 0' & 0 \end{pmatrix}\right) \neq 0$, then 8 necessarily divides $r$, $T$ being $r$-rowed, positive-definite, of determinant 1 and integral with even diagonal elements. Thus if 8 does not divide $r$, repeated application of (5)’
eventually yields a primitive \( T_0 \) with non-zero \( a\left(\begin{pmatrix} T_0 & 0 \\ 0 & 0 \end{pmatrix}\right) \), since \( f \neq 0 \) (and \( \Phi(f) \neq 0 \), as a result). For such a \( T_0 \), we deduce from (7) and (8) that \( \det T_0 = 1 \) and \( r \equiv 0 \)(mod 8), which is a contradiction. The first assertion of the theorem is thus proved for \( s = r + 1 \) and hence for every \( s \geq r + 1 \).

Let us now suppose that \( r \) is a (positive) multiple of 8. For the given \( f \in \{ \Gamma_{r+1}, r/2 \} \), we can always find a constant \( u_i \) such that the Fourier coefficient \( a\left(\begin{pmatrix} S_i & 0 \\ 0 & 0 \end{pmatrix}\right) \) of \( f \) is precisely \( u_i E(S_i) \) for \( 1 \leq i \leq h \). Let, for given \( r \)-rowed integral symmetric \( R \), \( A(S_i, R) \) denote the number of integral matrices \( G \) for which \( S_i[G] = R \). It is immediate from the choice of \( u_i(1 \leq i \leq h) \) that for \( \det T = 1 \),

\[
a\left(\begin{pmatrix} T & 0 \\ 0 & 0 \end{pmatrix}\right) = \sum_{1 \leq i \leq h} u_i A(S_i T) \quad (10)
\]

Indeed, \( T \) is in the \( \mathbb{Z} \)-equivalence class of exactly one of \( S_1, \ldots, S_n \) and (10) follows from the choice of \( u_i \) and from the fact that \( f(B'WB) = f(W) \) for integral \( B \) of determinant \( \pm 1 \). Assume that (10) has been proved for all integral positive definite \( T \) with even diagonal elements and \( \det T < t \). Then from (5)', if \( \det T = t \),

\[
(1 - 1/(\det T)^{1/2}) a\left(\begin{pmatrix} T & 0 \\ 0 & 0 \end{pmatrix}\right) = \frac{1}{(\det T)^{1/2}} \sum_{(d,c) \mid |\det d| \neq 1} a\left(\begin{pmatrix} T[d^{-1}] & 0 \\ 0 & 0 \end{pmatrix}\right) = (1/(\det T)^{1/2}) \sum_{(d,c) \mid |\det d| \neq 1} u_i A(S_i, T[d^{-1}]).
\]

using the hypothesis on (10). But the last expression is just 271

\[
(1 - 1/(\det T)^{1/2}) \sum_{1 \leq i \leq h} u_i A(S_i, T)
\]

since \( \sum_{1 \leq i \leq h} u_i A(S_i, T) \) is itself the Fourier coefficient of

\[
\sum_{1 \leq i \leq h} u_i t(W; S_i) \in \{ \Gamma_{r+1}, r/2 \}
\]
corresponding to \( \begin{pmatrix} T & 0 \\ 0 & 0 \end{pmatrix} \) and consequently satisfies \((5)\)’. As a result, we have

\[
a \left( \begin{pmatrix} T & 0 \\ 0 & 0 \end{pmatrix} \right) = \sum_{1 \leq i \leq h} u_i A(S_i, T)
\]

for \( \det T \geq 1 \). In other words,

\[
(\Phi(f))(Z) = \sum_{1 \leq i \leq h} u_i t(Z, S_i)
\]

\[
= \Phi \left( \sum_{1 \leq i \leq h} u_i t(W, S_i) \right)
\]

i.e.

\[
f(W) = \sum_{1 \leq i \leq h} u_i t(W, S_i)
\]

which completes the proof of the theorem for \( s = r + 1 \).

**Acknowledgement.** We are grateful to Prof. H.L. Resnikoff for having sent a preprint entitled ‘Stable spaces of modular forms’. It may be remarked that relations (3.7) and (3.8) on page 8 of that preprint do not seem to be correct.

We learned from Prof. H. Klingen in December 1976 that Freitag and Resnikoff have independently proved the assertion: “singular modular forms are generated by theta series”. Perhaps, their proof is also on the same lines as above. We received recently a preprint of D. M. Cohen and H. Resnikoff entitled “Hermitian quadratic forms and hermitian modular forms”; this contains a reference to a preprint of H. L. Resnikoff entitled “The structure of spaces of singular automorphic forms” the contents of which are, however, not known to us.

Contre-Exemple Au “Vanishing Theorem” En Caractéristique $p > 0$

par M. Raynaud

Sorr $k$ un corps algébriquement clos de caractéristique $p > 0$. Nous allons construire une surface $X$, propre et lisse sur $k$, et un faisceau inversible ample $\mathcal{I}$ sur $X$, tel que $H^1(X, \mathcal{I}^{-1}) \neq 0$. Ainsi le théorème de Kodaira [2], ne s’étend pas en caractéristique $p > 0$. Ce contre-exemple est à rapprocher de celui obtenu par Mumford avec une surface normale, non lisse [5].

On va construire la surface $X$ comme fibrée sur une courbe $C$, avec des fibres intégrales et une ligne horizontale de “cusps”. Ces fibres sont les complétions projectives de courbes affines d’équation $y^2 = x^p + a$, si $p \neq 2$ et $y^3 = x^2 + a$ si $p = 2$.

Je tiens à remercier messieurs Oda et Spiro pour l’aide précieuse qu’ils m’ont apportée dans l’élaboration de ce travail.

1 Frobenius sur les courbes

On reprend ici une petite partie des résultats de Tango [6].

Soit $C$ une courbe propre et lisse sur $k$, de genre $g$, de corps des fractions $K$ et soit $F : C' \to C$ le $k$-morphisme radiciel de degré $p$, correspondant à la fermeture intégrale de $C$ dans $K' = K^{1/p}$. La différentielle

$$d : \mathcal{O}_{C'} \to \Omega^1_{C'}$$
donne des suites exactes de $\mathcal{O}_C$-modules:

$$
0 \to \mathcal{O}_C \to F_*(\mathcal{O}_{C'}) \xrightarrow{\alpha} \mathcal{B}^1 \to 0 \quad \text{(1)}
$$

$$
0 \to \mathcal{B}^1 \to F_*(\Omega^1_{C'}) \xrightarrow{c} \Omega^1_{C} \to 0 \quad \text{(2)}
$$

ou $c$ est l’opération de Cartier.

Soit $\mathcal{L} \subset \mathcal{B}^1$ un $\mathcal{O}_C$-module inversible et $l$ son degré. Si $\mathcal{E} = \alpha^{-1}(\mathcal{L})$, on a une suite exacte:

$$
0 \to \mathcal{O}_C \to \mathcal{E} \to \mathcal{L} \to 0, \quad \text{(3)}
$$

d’ou un morphisme de $\mathcal{O}_C$-algèbres

$$
S(\mathcal{E}) \xrightarrow{\beta} F_*(\mathcal{O}_{C'})
$$

(on désigne par $S(\mathcal{E})$ l’algèbre symétrique de $\mathcal{E}$, par $S^n(\mathcal{E})$, sa partie homogène de degré $n$).

**Proposition 1.** (i) On a $l \leq 2(g - 1)/p$, avec égalité si et seulement si $\beta$ est surjectif.

(ii) Pour qu’il existe un diviseur $D$ sur $C$ avec $\mathcal{L} \cong \mathcal{O}_C(D)$, il faut et il suffit qu’il existe $f \in K$ avec $(df) \geq pD$, $df \neq 0$.

**Démonstration.** Les courbes $C$ et $C'$ ayant même genre, la caractéristique d’Euler-Poincaré de $\mathcal{B}^1$ est nulle, d’où, par Riemann Roch:

$$
\deg(\mathcal{B}^1) + (p - 1)(1 - g) = 0.
$$

Par ailleurs, $\beta(S(\mathcal{E}))$ est isomorphe à $S^{p-1}(\mathcal{E})$, donc $\alpha \circ \beta(S(\mathcal{E}))$ est un sous-faisceau de $\mathcal{B}^1$ qui admet une filtration, a quotients successifs isomorphes à $\mathcal{L}^\otimes i$, $1 \leq i \leq (p - 1)$. On a donc $lp(p - 1)/2 \leq (p - 1)(g - 1)$, soit $l \leq 2(g - 1)/p$, avec égalité si et seulement si $\beta$ est surjectif, d’où (i).

Prouvons (ii). On a $\mathcal{L} \cong \mathcal{O}_C(D) \Rightarrow H^0(C, \mathcal{B}^1(-D)) \neq 0$. En tensorisant (2) par $\mathcal{O}_C(-D)$, on trouve la suite exacte:

$$
0 \to \mathcal{B}^1(-D) \to F_*(\Omega^1_{C'}(-F^*(D))) \xrightarrow{c(-D)} \Omega^1_{C}(-D) \to 0
$$
Par suite, $H^0(C, \mathcal{B}^1(-D)) = \{df', f' \in K', (df') \geq F^*(D)\}$.

Par l’élévation à la puissance $p$, cet ensemble est en bijection avec

$$\{df, f \in K, (df) \geq pD\}, \quad \text{d’ou (ii).}$$

**Corollaire.** Pour qu’il existe $\mathcal{L}$ dans $\mathcal{B}^1$, avec $\mathcal{L} \simeq \mathcal{O}_C(D)$ deg $(D) = 2(g - 1)/p$, il faut et il suffit qu’il existe $f \in K$, avec $(df) = pD$.

**Exemple.** Soit $h$ un entier $> 0$ et considérons le revêtement d’Artin-Schreier de la droite affine, d’équation:

$$X^p - X = T^{hp-1}.$$ 

Soit $C$ la complétion projective de ce revêtement, munie de son point à l’infini. La différente $\mathcal{D}$ est égale à $hp(p-1)\infty$, la courbe $C$ est de genre $g$ avec $2(g-1) = p(h(p-1)-2)$ et $(dT) = p(h(p-1)-2)\infty$. On peut donc prendre $\mathcal{L} = \mathcal{O}_C(D)$ avec $D = (h(p-1)-2)\infty$.

### 2 Construction de $(X, \mathcal{I})$

Désormais, on suppose donnés $C$ de genre $g > 1$ et $\mathcal{L}$ satisfaisant aux conditions énoncées dans le corollaire, donc de degré $1 = 2(g - 1)/p > 0$.

Soit $P = P(\mathcal{E})$ le fibré en droites projectives sur $C$, défini par $\mathcal{E}$. Notons $f : P \rightarrow C$ le morphisme structural et $\mathcal{O}_P(1)$ le faisceau inversible relativement ample canonique. On a $f_*(\mathcal{O}_P(n)) = S^n(\mathcal{E})$. Enfin, le faisceau dualisant relatif est $\omega_{P/C} = \mathcal{O}_P(-2) \otimes \Lambda^2(\mathcal{E}) = \mathcal{O}_P(-2) \otimes \mathcal{L}$.

On a deux diviseurs horizontaux naturels sur $P$. Tout d’abord, le quotient $\mathcal{L}$ de $\mathcal{E}$, définit une section de $f$; soit $E \simeq C$ son image. L’élément $1$ de $\mathcal{O}_C$, vu comme élément de $H^0(C, \mathcal{E}) = H^0(P, \mathcal{O}_P(1))$, donne une section $s$ de $\mathcal{O}_P(1)$, qui s’annule sur $E$ et fournit un isomorphisme de $\mathcal{O}_P(1)$ avec $\mathcal{O}_P(E)$. Par ailleurs, si on tensorise $[3]$ avec le morphisme de Frobénius absolu sur $C$, on
obtient la suite exacte:

\[ 0 \to \mathcal{O}_C \to \mathcal{E}^{(p)} \to \mathcal{L}^{\otimes p} \to 0. \]  

(4)

Comme \( \mathcal{E} \subset \mathcal{O}_C' \), l'élévaton à la puissance \( p \) dans \( \mathcal{O}_C' \), permet de définir un morphisme \( \mathcal{O}_C \)-linéaire surjectif \( \mathcal{E}^{(p)} \to \mathcal{O}_C \); son noyau est isomorphe à \( \mathcal{L}^{\otimes p} \) et fournit un scindage de (4). On a donc une droite canonique \( \mathcal{L}^{\otimes p} \) dans \( \mathcal{E}^{(p)} \subset \mathcal{S}^p(\mathcal{E}) = p_*(\mathcal{O}_p(p)). \)

D'où une section \( t \in H^0(P, \mathcal{O}_p(p) \otimes \mathcal{L}^{\otimes -p}); \) t s'annule sur une courbe de \( P \), de degré \( p \) sur \( C \) qui, compte tenu du choix de \( \mathcal{L} \), est \( C \)-isomorphe à \( C' \) (et on la note \( C' \) dans la suite), donc est lisse sur \( k \). Enfin on a \( C' \cap E = \emptyset \).

**Examinons d'abord le cas \( p \neq 2 \).** On va construire un revêtement \( X \) de \( P \), de degré 2, ramifié le long de \( C' \cup E \). Pour cela, on choisit \( N \) inversible sur \( C \), tel que \( N^{\otimes 2} = \mathcal{L} \) (noter que \( l \) est pair). Pour décrire le morphisme \( \pi : X \to P \), on doit se donner un faisceau inversible \( \mathcal{M} \) sur \( P \) et un isomorphisme de \( \mathcal{M}^{\otimes 2} \) avec \( \mathcal{O}_P(-E - C') \); on a alors \( \pi_*(\mathcal{O}_X) = \mathcal{O}_P \oplus \mathcal{M} \). On prend \( \mathcal{M} = \mathcal{O}_P(-(p + 1)/2) \otimes N^{\otimes p} \) et le morphisme de \( \mathcal{O}_P \) dans \( \mathcal{M}^{\otimes 2} = \mathcal{O}_P(p + 1) \otimes \mathcal{L}^{\otimes -p} = \mathcal{O}_P(E + C') \) défini par \( s \otimes t \). Comme \( C' \) et \( E \) sont lisses sur \( k \), et disjointes, \( X \) est lisse sur \( k \). Les fibres de \( g = f \circ \pi \) sont de genre \( (p - 1)/2 \); un calcul local montre que \( X \) possède une ligne de cusps \( \tilde{C} \), au-dessus de \( C' \) (\( \tilde{C} \) isomorphe à \( C' \)). En dehors de \( \tilde{C} \), \( X \) est lisse sur \( C \). Enfin \( E \) se dédouble sur \( X \) en \( \pi_*(E) = 2\tilde{E} \).

**Lemme.** Il existe \( n > 0 \) tel que \( \mathcal{O}_X(n\tilde{E}) \) soit engendré par ses sections. Le système linéaire correspondant contracte une seule courbe: la ligne de cusps \( \tilde{C} \).

Evidemment, la section de \( \mathcal{O}_X(\tilde{E}) \) engendre \( \mathcal{O}_X(\tilde{E}) \) en dehors de \( \tilde{E} \). Donc \( \tilde{C} \), qui est contenue dans \( X - \tilde{E} \), sera nécessairement contractée. Par ailleurs on a \( \pi_*(\mathcal{O}_X(\tilde{E})) = \mathcal{O}_P \oplus \mathcal{M}(E) \) et plus généralement, pour \( n \geq 0 \), on a

\[ \pi_*\mathcal{O}_X(2n\tilde{E}) = \mathcal{O}_P(nE) \oplus \mathcal{M}(nE) \] et \( \pi_* \mathcal{O}_X((2n + 1)\tilde{E}) \)
\[ = \mathcal{O}_P(nE) \oplus \mathcal{M}((n \oplus 1)E). \]

En particulier
\[ g_*(\mathcal{O}_X(p\mathcal{E})) = p_*(\mathcal{O}_P((p - 1/2)E) \oplus \mathcal{M}((p + 1/2)E)) \]
\[ = p_*(\mathcal{O}_P((p - 1)/2)) \oplus \mathcal{N}^{\oplus n}. \]

Comme \( \mathcal{N} \) est de degré > 0, \( \mathcal{N}^{\oplus pm} \) est engendré par ses sections pour \( m \gg 0 \). Si alors \( \sigma \) engendre \( \mathcal{N}^{\oplus pm} \) au-dessus d’un ouvert affine \( U \) de \( C \), il correspond à \( \sigma \) une section de \( \mathcal{O}_X(pm \mathcal{E}) \), qui engendre ce faisceau au-dessus de \( U \), en dehors de \( \mathcal{C} \), donc sur un ouvert affine de \( X \), d’où le lemme.

Il résulte du lemme que, si \( \mathcal{D} \) est un faisceau inversible sur \( C \), de degré > 0, alors \( \mathcal{L} = \mathcal{O}_X(\mathcal{E}) \otimes g(\mathcal{D}) \) est ample sur \( X \). Il nous reste à voir que l’on peut choisir \( \mathcal{D} \), de degré > 0, de façon que \( H^1(X, \mathcal{D}^{-1}) \) soit \( \neq 0 \). On a \( H^1(X, \mathcal{O}_X(-\mathcal{E}) \otimes \mathcal{D}^{-1}) = H^0(C, R^1 g_*(\mathcal{O}_X(\mathcal{E})) \otimes \mathcal{D}^{-1}) \); \( R^1 g_*(\mathcal{O}_X(\mathcal{E})) = R^1 p_*(\mathcal{O}_P(-E) \oplus \mathcal{M}) = R^1 p_*(\mathcal{M}) \). Vu la dualité de Serre, \( R^1 p_*(\mathcal{M}) \) est dual de \( \mathcal{L}^{\oplus (p-3)/2} \otimes \mathcal{N}^{\oplus (2-p)} = \mathcal{N}^{-1} \), donc \( R^1 g_*(\mathcal{O}_X(-\mathcal{E})) \otimes \mathcal{D}^{-1} \) contient \( \mathcal{N} \otimes \mathcal{D}^{-1} \). Il suffit donc de prendre \( \mathcal{D} \) de degré > 0, tel que \( H^0(C, \mathcal{N} \otimes \mathcal{D}^{-1}) \neq 0 \), par exemple \( \mathcal{D} = \mathcal{N} \).

Dans le cas \( p = 2 \), on choisit \( l = g - 1 \) multiple de 3 et un faisceau inversible \( \mathcal{N} \) sur \( C \) tel que \( \mathcal{N}^{\otimes 3} = \mathcal{L} \). On prend pour \( \mathcal{M} \) un revêtement cyclique de degré 3 de \( P \), ramifié le long de \( E \cup C' \), défini par le faisceau inversible \( \mathcal{M} = \mathcal{O}_P(-1) \otimes \mathcal{N}^2 \) et le morphisme

\[ \mathcal{O}_P \to \mathcal{M}^{\otimes -3} = \mathcal{O}_P(3) \otimes \mathcal{L}^{-2} = \mathcal{O}_P(E + C') \]

défini par \( s \otimes t \). La fin de la démonstration est analogue à celle du cas \( p \neq 2 \).

### 3 Remarques et questions

1. La surface \( X \) que nous avons construite est un revêtement radi-
ciel de degré $p$ d’une surface réglée de base $C$; en particulier, elle a pour nombres de Betti, $b_1 = 2g$, $b_2 = 2$. Néanmoins, du point de vue de la classification d’Enriques, Bombieri, Mumford [1] et [4], elle est de type général pour $p \geq 5$, quasi-elliptique (avec $\chi(\mathcal{O}_X) < 0$) pour $p = 2$ et 3.

2. Comme $E$ est une section de $f$, $\omega_{\mathcal{P}/C(E)|E}$ est trivial, donc $\mathcal{O}_p(E)|E$ est isomorphe à $\mathcal{L}|C$; en particulier $E^2 = l > 0$. Il en résulte que l’on a $\bar{E}^2 = l/2$ pour $p \neq 2$ et $\bar{E}^2 = l/3$ pour $p = 2$. Mumford et Spiro ont remarqué que, des que l’on avait une surface lisse $X$, fibrée sur une courbe $C$, à fibres intégrales de genre $\geq 1$ munie d’une section $E$ telle que $E^2 > 0$, on pouvait trouver sur $X$, un faisceau ample $\mathcal{L}$ tel que $H^1(X, \mathcal{L}^{-1}) \neq 0$.

3. Dans le revêtement d’Artin-schreier cité plus haut prenons, $h = ap - 2$ avec $a \geq 1$ si $p \geq 5$, $a \geq 2$ si $p = 3$ et prenons $h = 8$ si $p = 2$. On peut alors choisir $\mathcal{N} = \mathcal{O}_C(a(p-1/2)-1)p\infty$ si $p \geq 3$ et $\mathcal{N} = \mathcal{O}_C(2\infty)$ si $p = 2$ et prendre pour faisceau ample $\mathcal{I} = \mathcal{O}_X(\bar{E}) \otimes \mathcal{N}$. Comme $\mathcal{N}$ est engendré par ses sections sur $C$ (car image réciproque sur $C$ d’un faisceau sur la droite projective), $\mathcal{L}$ est alors engendré par ses sections en dehors de $\bar{E}$. Peut-on contre-exempler le théorème de Kodaira avec un faisceau ample, engendré par ses sections, voir très ample?

4. Soient $X$ une variété propre et lisse sur $k$, $\mathcal{L}$ un faisceau ample sur $X$ et $\omega$ le faisceau dualisant. Supposons que $X$ et $\mathcal{L}$ se relèvent en caractéristique zéro. Il résulte alors du théorème de Kodaira et des propriétés de spécialisation de la cohomologie que pour tout entier $i \geq 0$, on a:

$$\chi^i(X, \mathcal{L} \otimes \omega) = \dim H^i(X, \mathcal{L} \otimes \omega) - \dim H^{i+1}(X, \mathcal{L} \otimes \omega) + \cdot \geq 0.$$

Ces propriétés restent-elles variées sans hypothèses de relèvement? Notons qu’un tel résultat; bien que nettement plus faible que le théorème de Kodaira, suffirait pour étendre à la caractéristique $p$, le théorème de finitude de Matsuaka [3].

The Tricanonical Map of a Surface with 
\( K^2 = 2, \, P_g = 0 \)

By E. Bombieri and F. Catanese

1 Introduction

In this paper we prove the following result.

**Theorem 1.** Let \( S \) be a minimal surface of general type with \( K^2 = 2, \, P_g = 0 \), over an algebraically closed field \( k \), \( \text{char}(k) = 0 \). Then the tricanonical map \( \Phi_{3K} \) of \( S \) is a birational morphism.

If we combine Theorem 1 with the results of Bombieri ([1] referred in the sequel as [CM]) and Miyaoka [4] we deduce

**Theorem 2.** If \( S \) is a minimal surface of general type over an algebraically closed field \( k \), \( \text{char}(k) = 0 \) and \( m \geq 3 \), then \( \Phi_{mK} \) is a birational map with exactly the following exceptions:

(a) \( m = 3, \, K^2 = 1 \) and \( P_g = 2, \, K^2 = 2 \) and \( P_g = 3 \)

(b) \( m = 4, \, K^2 = 1 \) and \( P_g = 2 \).

We refer to Horikawa [3] for a detailed and exhaustive study of the surfaces in (a) and (b)†

†Added in Proof. The result of Theorem 2 has been independently obtained by X. Benveniste, with a similar method.
$K$ a canonical divisor on $S$,
$\omega_D$ the dualizing sheaf of a divisor $D > 0$ on $S$, hence

$$\omega_D \cong \mathcal{O}_D(D + K),$$

$\mathcal{O}$ the structure sheaf of $S$,
$$\mathcal{F}(-C - a_1x_1 - \cdots - a_rx_r)$$
the sheaf of germs of sections of $\mathcal{F}$ vanishing on $C$ and on $x_i$ with multiplicity $a_i$,

$$\mathcal{F}_C(-a_1x_1 - \cdots - a_rx_r) = \mathcal{F}/\mathcal{F}(-C - a_1x_1 - \cdots - a_rx_r),$$

$$|D - C - a_1x_1 - \cdots - a_rx_r| = \text{Proj}
H^0(\mathcal{O}(D - C - a_1x_1 - \cdots - a_rx_r)) \subseteq |D|p(D)$$

$$p(D) = \frac{1}{2}(D^2 + KD) + 1$$

the arithmetic genus of $D$; $P_m$ the plurigenera of $S$.

### 2 Two auxiliary results

The first result of this section gives a necessary condition for an invertible sheaf on a curve $C$ on a surface $X$ to have a section. The technique of proof is one invented by C.P. Ramanujam in the study of numerically connected divisors.

**Proposition A.** Let $C > 0$ be a divisor on a smooth surface $X$ and let $\mathcal{L}$ be an invertible sheaf on $C$ with $H^0(C, \mathcal{L}) \neq (0)$.

Then either

(i) $\deg_C \mathcal{L} \geq 0$,

or

(ii) we have $C = C_1 + C_2$, $C_i > 0$ with

$$C_1C_2 \leq \deg_{C_2}(\mathcal{L} \otimes \mathcal{O}_{C_2}).$$

Moreover, (ii) holds whenever there is a section $s$ of $\mathcal{L}$ vanishing on $C_1$ but not on any $C'$ with $C_1 < C' < C$. 
\textit{The Tricanonical Map of a Surface with } K^2 = 2, P_g = 0

\textbf{Proof.} Let } s \in H^0(C, \mathcal{L}) \text{ and suppose that the restriction of } s \text{ to any irreducible component of } C \text{ is never identically 0. Let } C = \sum n_i \Gamma_i, \Gamma_i \text{ irreducible, so that }

\deg_C \mathcal{L} = \sum n_i \deg_{\Gamma_i}(\mathcal{L} \otimes \mathcal{O}_{\Gamma_i}).

If \deg_C \mathcal{L} < 0, we would get \deg_{\Gamma_i}(\mathcal{L} \otimes \mathcal{O}_{\Gamma_i}) < 0 \text{ for some } i, \text{ hence } \mathcal{L} \otimes \mathcal{O}_{\Gamma_i} \text{ would have only the 0-section since } \Gamma_i \text{ is irreducible. This however contradicts our initial assumption that the restriction of } s \text{ to } \Gamma_i \text{ is not identically 0, i.e. that } s \text{ is not in the kernel of the restriction map }

H^0(C, \mathcal{L}) \xrightarrow{\text{res}} H^0(\Gamma_i, \mathcal{L} \otimes \mathcal{O}_{\Gamma_i}).

It follows that if conclusion (i) does not hold then there is } C_1, \text{ with } 0 < C_1 < C \text{ such that } s \text{ is in the kernel of the restriction map }

H^0(C, \mathcal{L}) \xrightarrow{\text{res}} H^0(C_1, \mathcal{L} \otimes \mathcal{O}_{C_1}).

According to Ramanujam’s idea, we take a \textit{maximal } C_1 \text{ and verify two exact sequences of sheaves }

\begin{align*}
0 & \rightarrow \mathcal{O}_{C_2} \xrightarrow{s} \mathcal{L} \rightarrow \mathcal{L}/s\mathcal{O}_C \rightarrow 0 \\
0 & \rightarrow \mathcal{F} \rightarrow \mathcal{L}/s\mathcal{O}_C \rightarrow \mathcal{L} \otimes \mathcal{O}_{C_1} \rightarrow 0
\end{align*}

where } C_1 + C_2 = C \text{ and where the sheaf } \mathcal{F} \text{ is supported at finitely many points. Now we take the total Chern class on } X \text{ of the above sequences and find }

\[ c(\mathcal{L}) = c(\mathcal{O}_{C_2})c(\mathcal{L}/s\mathcal{O}_C) = c(\mathcal{O}_{C_2})c(\mathcal{L} \otimes \mathcal{O}_{C_1})c(\mathcal{F}) \]

whence the equation

\[ 1 + C + (C^2 - \deg_C \mathcal{L}) \]

\[ = (1 + C_2 + C_2^2)(1 - \text{length } \mathcal{F})(1 + C_1 + C_1^2 - \deg_{C_1} \mathcal{L}) \]
in the Chow ring of \( X \). The equation in degree 2 is simply

\[ C_1C_2 + \text{length } \mathcal{F} = \deg_{C_2} \mathcal{L} \]

and our result is prove. \( \square \) (QED)

Our next result, the fact that the canonical system of an irreducible curve has no base points is very classical, but since we could not find an adequate reference we give a proof here.

**Proposition B.** If \( \Gamma \) is an irreducible Gorenstein curve and \( |\omega_{\Gamma}| \neq \emptyset \), then \( |\omega_{\Gamma}| \) has no base points. More generally, a reduced point \( p \) on a reducible curve \( C \) on a smooth surface is not a base point of \( |\omega_C| \) if either

(i) \( p \) is simple on \( C \) and belongs to a component \( \Gamma \) with \( p(\Gamma) \geq 1 \) or

(ii) \( p \) is singular and for every decomposition \( C = C_1 + C_2 \) one has

\[ C_1C_2 > (C_1 \cdot C_2)_p, \]

where \((C_1 \cdot C_2)_p\) is the intersection multiplicity of \( C_1, C_2 \) at \( p \).

We begin by proving

**Lemma B’.** Let \( p \) be a singular point of a curve \( C \) lying on a smooth surface \( S \), let \( m_p \) be the maximal ideal of \( p \) and let \( \pi : \widetilde{C} \to C \) be a normalization of \( C \) at \( p \). Then \( \text{Hom}(m_p, \mathcal{O}_{C,p}) \), can be embedded in the ring \( A \) of regular functions on \( \pi^{-1}(p) \), i.e.

\[ A = \bigoplus_{\pi(p')=p} \mathcal{O}_{\widetilde{C},p}. \]

**Proof.** Let \( \varphi \in \text{Hom}(m_p, \mathcal{O}_{C,p}) \) and let \( x, y \) be local parameters for \( S \) at \( p \). We denote by \( f \) a local equation for \( C \) at \( p \) and for \( u \in \mathcal{O}_p \) we denote by \([u]\) its image in \( \mathcal{O}_{C,p} = \mathcal{O}_p/(f) \). We may and shall assume that \([x]\) and \([y]\) are not 0-divisors in \( \mathcal{O}_{C,p} \). The
The Tricanonical Map of a Surface with $K^2 = 2$, $P_g = 0$ 331

homomorphism $\varphi$ is determined by the knowledge of $\varphi([x])$ and $\varphi([y])$; let $\xi$ and $\eta$ be such that

$$[\xi] = \varphi([x]), \quad [\eta] = \varphi([y]).$$

We have $\varphi([xy]) = [x][\eta] = [\xi][y]$ thus $[\eta] = [\xi][y]/[x]$ in the ring of quotients of $\mathcal{O}_{C,p}$. It follows that we have a bijection between $\varphi$’s and classes $[\xi]$ such that

$$[\xi][y]/[x] \in \mathcal{O}_{C,p},$$

since for every $[z] \in m_p$ we may set

$$\varphi([z]) = [z][\xi]/[x].$$

Let $p' \in \pi^{-1}(p)$ and let $t$ be a local parameter on $\widetilde{C}$ at $p'$. Then we claim that

$$\text{ord}_t \pi^*([\xi]/[x]) \geq 0.$$

In fact, suppose that $\text{ord}_t \pi^*\xi < \text{ord}_t \pi^*x \leq \text{ord}_t \pi^*y$; then we cannot have $\xi \in m_p$, hence $[\xi]$ is a unit and $[y] = [x][\eta]/[\xi]$, which shows that the maximal ideal of $\mathcal{O}_{C,p}$ is generated by $[x]$, i.e. $p$ is a regular point of $C$. If instead $\text{ord}_t \pi^*y < \text{ord}_t \pi^*x$, there is the same reasoning with $\eta$ and $y$ instead of $\xi$ and $x$, because $[\eta]/[y] = [\xi]/[x]$.

Q.E.D.

Now we can prove Proposition 3

If $p$ is a base point of $|\omega_C|$ the exact sequence

$$0 \to \omega_C m_p \to \omega_C \to k_p \to 0$$

yields

$$0 \to k \to H^1(C, \omega_C m_p) \to H^1(C, \omega_C) \to 0.$$

By Grothendieck’s Deuality we obtain

$$0 \leftarrow k \leftarrow \text{Hom}(m_p, \mathcal{O}_C) \leftarrow H^0(C, \mathcal{O}_C) \leftarrow 0$$

283
and
\[ \dim \text{Hom}(m_p, \mathcal{O}_C) \geq 2. \]

In Case (i), \( \text{Hom}(m_p, \mathcal{O}_C) \cong H^0(C, \mathcal{O}_C(p)) \) hence \( \dim H^0(\Gamma, \mathcal{O}_C(p)) \geq 2 \) and \( p(\Gamma) = 0 \), that is \( \Gamma \) is rational non-singular.

In Case (ii), by Lemma B', \( \text{Hom}(m_p, \mathcal{O}_C) \) embeds into \( H^0(\widetilde{C}, \mathcal{O}_{\widetilde{C}}) \), and the condition of (ii) implies that \( \widetilde{C} \) is numerically connected on a smooth surface, thus \( \dim H^0(\widetilde{C}, \mathcal{O}_{\widetilde{C}}) = 1 \) by a result of C.P. Ramanujam [6]; this contradicts \( \dim \text{Hom}(m_p, \mathcal{O}_C) = 2. \) Q.E.D.

3 The linear system

\[ |2K-x-y| \]. It is clear, since \( P_2 = 3 \), that for any two points \( x, y \in S \) the linear system \( |2K-x-y| \) is non-empty. We denote by \( \Phi \) the tricanonical map \( \Phi_{3K} \) and assume that \( \Phi \) is not birational. Hence let \( x \) be a general point of \( S \) and let \( y \) be such that \( \Phi(x) = \Phi(y) \). We denote by \( C \) a divisor in \( |2K-x-y| \) and, in case \( \dim |2K-x-y| = 1 \), we also choose \( C \) as a general element.

**Lemma 1.** We have \( h^1(\mathcal{O}_C(3K-x-y)) = 2. \)

**Proof.** Since \( \Phi(x) = \Phi(y) \) the cohomology sequences of
\[
0 \rightarrow \mathcal{O}(3K-x-y) \rightarrow \mathcal{O}(3K) \rightarrow k_x \oplus k_y \rightarrow 0 \\
0 \rightarrow \mathcal{O}(3K-C) \rightarrow \mathcal{O}(3K-x-y) \rightarrow \mathcal{O}_C(3K-x-y) \rightarrow 0
\]
yield
\[
h^1(\mathcal{O}_C(3K-x-y)) = h^1(\mathcal{O}(3K-x-y)) + h^2(\mathcal{O}(3K-C)) \\
= 1 + h^2(\mathcal{O}(K)) = 2,
\]
because \( h^1(\mathcal{O}(3K-C)) = h^1(\mathcal{O}(K)) = 0. \) Q.E.D.

The curve \( C \) may be reducible and we shall denote by \( \Gamma \) an irreducible component containing \( x \) or \( y \). We then have that \( K\Gamma \geq \)
2, because $K \Gamma \leq 1$ would imply $\Gamma^2 < 0$ by the Index Theorem, while there are only finitely many such curves on $S$ ([CM], page 176). Since $KC = 4$ we deduce that either $x$ and $y$ lie on only one component $\Gamma$ of $C$ or that they belong to exactly two components. Thus we distinguish two cases:

(A) $C = \Gamma_1 + \Gamma_2 + M$, where $K \Gamma_i = 2$, $\Gamma_i^2 \geq 0$, $KM = 0$ and $x \in \Gamma_1, y \in \Gamma_2$ (possibly $\Gamma_1 = \Gamma_2$);

(B) $C = \Gamma + M$ where $x, y \in \Gamma$ and $x, y \not\in M$.

**Lemma 2.** If case (A) holds then $C = C_1 + C_2$ with $C_1 \sim C_2 \sim K$, $\Gamma_1 \leq C_1$, $\Gamma_2 \leq C_2$ and either

(a) $C_1 \neq C_2$, in which case $\Gamma_1$ and $\Gamma_2$ intersect transversally exactly at $x$ and $y$, or

(b) $C_1 = C_2$.

**Proof.** We shall prove Lemma 2 in several steps.

**Step 1.** $x$ and $y$ belong to both $\Gamma_1$ and $\Gamma_2$.

In order to prove this, we shall assume that $x \not\in \Gamma_2$ and derive a contradiction.

First of all, we have

$$h^0(\mathcal{O}(3K - \Gamma_2 - M - x)) = h^0(\mathcal{O}(3K - \Gamma_2 - M)) - 1.$$ 

In fact, since $x \not\in \Gamma_2 + M$, if the above assertion were not true then we would have

$$h^0(\mathcal{O}(K + \Gamma_1 - x)) = h^0(\mathcal{O}(K + \Gamma_1))$$

i.e., $x$ would be a base point of $|K + \Gamma_1|$. Since $p_g = 0$, the restriction map gives an isomorphism

$$H^0(\mathcal{O}(K + \Gamma_1)) \sim H^0(\mathcal{O}(\omega_{\Gamma_1}))$$
and noting that $|K + \Gamma_1|$ is non-empty ($p(\Gamma_1) > 0$) and that $\Gamma_1$ is never a component of elements of $|K + \Gamma_1|$ (since $p_\mathcal{G} = 0$) we deduce that $x$ is a base point of $H^0(\omega_{\Gamma_1})$; this however contradicts Proposition B.

Next, we note that

$$h^i(\mathcal{O}(3K - \Gamma_2 - M)) = 0$$

for $i = 1, 2$, because

$$h^i(\mathcal{O}(3K - \Gamma_2 - M)) = h^i(\mathcal{O}(K + \Gamma_1)) = h^{2-i}(\mathcal{O}(-\Gamma_1)) = 0$$

for $i = 1, 2$ (in fact, $\Gamma_1$ is connected and $S$ has irregularity 0; then use ([CM], page 177). It now follows from the cohomology sequence of

$$0 \rightarrow \mathcal{O}(3K - \Gamma_2 - M - x) \rightarrow \mathcal{O}(3K - \Gamma_2 - M) \rightarrow k_x \rightarrow 0$$

that

$$h^i(\mathcal{O}(3K - \Gamma_2 - M - x)) = 0 \quad \text{for} \quad i = 1, 2.$$ 

Using this result and the cohomology sequence of

$$0 \rightarrow \mathcal{O}(3K - \Gamma_2 - M - x) \rightarrow \mathcal{O}(3K - x - y) \rightarrow \mathcal{O}_{\Gamma_2+M}(3K - y) \rightarrow 0$$

we deduce that

$$h^1(\mathcal{O}_{\Gamma_2+M}(3K - y)) = h^1(\mathcal{O}(3K - x - y)) = 1,$$

the latter equality because $\Phi(x) = \Phi(y)$ ([CM], p. 187).

By Grothendieck’s duality we get

$$\dim \text{Hom}(\mathcal{O}_{\Gamma_2+M}(\Gamma_1) \cdot m_y, \mathcal{O}_{\Gamma_2+M}) = 1.$$ 

If $\pi : \widetilde{S} \rightarrow S$ gives an embedded resolution of singularities of $\Gamma_2 + M$ at $y$ and if $\Gamma_2 + M$ is the corresponding curve on $\widetilde{S}$ then denoting by $\mathcal{L}$ the sheaf

$$\mathcal{L} = \begin{cases} \mathcal{O}_{\Gamma_2+M}(-\pi^*\Gamma_1) & \text{if } y \text{ is singular} \\ \mathcal{O}_{\Gamma_2+M}(-\Gamma_1 + y) & \text{if } y \text{ is simple} \end{cases}$$
we obtain $H^0(\tilde{\Gamma}_2 + M, \mathcal{L}) \neq (0)$, as one can see using Lamme [B].

Since $\deg \mathcal{L} \leq 1 - \Gamma_1(\Gamma_2 + M) < 0$ (note that $\Gamma_1 + \Gamma_2 + M \in |2K|$ is 2-connected, [CM], p. 181) we can apply Proposition [A] and obtain a decomposition

$$\tilde{\Gamma}_2 + M = A + B$$

where

$$AB \leq \deg_B(\mathcal{L} \otimes \mathcal{O}_B) \leq 1 - B\pi^*\Gamma_1.$$  

This leads to a contradiction: in fact, let $\pi^*\Gamma_2 = \tilde{\Gamma}_2 + H$; if $\tilde{\Gamma}_2 \subset B$, we get $(B + H)(A + \pi^*\Gamma_1) \leq 1$, while if $\tilde{\Gamma}_2 \subset A$, then $B(A + H + \pi^*\Gamma_1) \leq 1$ and in both cases one violates the 2-connectedness of $\Gamma_1 + \Gamma_2 + M$ ([CM], p. 81).

**Step 2.** The cohomology sequence of

$$0 \to \mathcal{O}(3K - \Gamma_2 - M) \to \mathcal{O}(3K - x - y) \to \mathcal{O}_{\Gamma_2 + M}(3K - x - y) \to 0$$

together with

$$h^i(\mathcal{O}(3K - \Gamma_2 - M)) = h^i(\mathcal{O}(K + \Gamma_1)) = h^{2-i}(\mathcal{O}(-\Gamma_1)) = 0$$

for $i = 1, 2$ gives

$$h^1(\mathcal{O}_{\Gamma_2 + M}(3K - x - y)) = 1.$$  

By Grothendieck’s duality one deduces

$$\dim \text{Hom}(\mathcal{O}_{\Gamma_2 + M}(\Gamma_1)m_xm_y, \mathcal{O}_{\Gamma_2 + M}) = 1$$

and, again by Lemma [B], we find that if $\pi : \tilde{S} \to S$ is an embedded resolution of singularities of $\Gamma_2 + M$ st $x$ and $y$ then $H^0(\tilde{\Gamma}_2 + M, \mathcal{L}) \neq (0)$ where $\mathcal{L}$ is the sheaf

$$\mathcal{L} = \mathcal{O}_{\tilde{\Gamma}_2 + M}(-\pi^*\Gamma_1 + ax + by)$$
where $a, b = 1$ or $0$ according as whether $x, y$ are simple or singular on $\Gamma_2$. Since $\Gamma_1 + \Gamma_2 + M$ is 2-connected we have

$$\deg \mathcal{L} \leq a + b - 2.$$ 

Two cases can occur:

(A) $\deg \mathcal{L} = 0$.

Then $a = b = 1$ and $x, y$ are simple on $\Gamma_2$ and $\Gamma_1(\Gamma_2 + M) = 2$; by Lemma 2 of [CM], p. 181 this implies

$$\Gamma_2 \sim \Gamma_1 + M \sim K.$$ 

Moreover in this case $\Gamma_1 \Gamma_2 = 2$ hence if $\Gamma_1 \neq \Gamma_2$ the two curves $\Gamma_1, \Gamma_2$ intersect transversally exactly at $x$ and $y$.

(B) $\deg \mathcal{L} < 0$.

Now we apply Proposition A and deduce that there is a decomposition

$$\tilde{\Gamma}_2 + M = A + B$$

where

$$AB \leq \deg_B(\mathcal{L} \otimes \mathcal{O}_B) \leq -B\pi^*\Gamma_2 + a + b.$$ 

This however implies, exactly as at the end of Step 1, that $a = b = 1$ and

$$(A + \Gamma_2)B = 2,$$

whence by Lemma 2 of [CM], p. 181 one finds again that $x, y$ are simple points of $\Gamma_2$ and

$$A + \Gamma_2 \sim B \sim K.$$ 

Since $KB = 2$ this implies that $\Gamma_1$ is a component of $B$, $x, y$ are simple on $\Gamma_1$ and $\Gamma_1\Gamma_2 = 2$. Finally, if $\Gamma_1 = \Gamma_2$ and if $B = B' + \Gamma_1$ then $A + \Gamma_2 \sim B' + \Gamma_1$, hence $A \sim B'$ and $A = B'$ ([CM], p. 175).

Q.E.D. □
Lemma 3. Case (A) does not hold.

Proof. Let \( x, y \) and \( C = C_1 + C_2 \in |2K - x - y| \) be as in Lemma 2. Recall that \( x, y \) was a general pair of points with \( \Phi_{3K}(x) = \Phi_{3K}(y) \) and \( C \) a general element with \( C \in |2K - x - y| \). By Lemma 2 there is a torsion class \( \tau \) such that \( C_1 \in |K + \tau| \); since the number of torsion classes is finite, and since \( x \) can be taken as a general point of the surface \( S \) we conclude that

\[
\dim |K \pm \tau| \geq 1.
\]

Now \( |K + \tau| + |K - \tau| \subseteq |2K| \) and \( \dim |2K| = P_2 - 1 = 2 \), thus we deduce that \( |2K| \) is composite of a pencil and \( |K + \tau| = |K - \tau| \), i.e. \( \tau \) is a 2-torsion class. We have shown that \( C_1, C_2 \in |K + \tau| \), since \( x, y \in C_1 \) by Lemma 2 we see that if \( C_2' \) is a general element of \( |K + \tau| \) then \( C_1 + C_2' \) is a general element in \( |2K - x - y| \). By Lemma 2 again, we obtain that \( x, y \in C_2', \) i.e. \( x, y \) are base points of \( |K + \tau| \). This is plainly impossible because \( x \) was a general point on \( S \). \( \square \)

Lemma 4. The points \( x, y \) are simple points of \( C \).

Proof. By Lemma 4, \( h^1(\mathcal{O}_C(3K - x - y)) = 2 \) and Grothendieck’s duality yields

\[
\dim \text{Hom}(m_xm_y, \mathcal{O}_C) = 2.
\]

Denoting by \( \pi : \tilde{S} \to S \) an embedded resolution of singularities of \( C \) at \( x \) and \( y \), by Lemma 4 we see that \( x, y \) cannot both be singular, otherwise we would have \( h^0(\mathcal{O}_{\tilde{C}}) = 2 \), while \( \tilde{C} \) is connected exactly as \( C \) (and now use Ramanujam’s result in [CM], p. 177).

If, say, \( x \) is simple and \( y \) singular we get \( h^0(\mathcal{O}_{\tilde{C}}(x)) = 2 \) and this implies that \( \Gamma \), the component of \( C \) with \( x \in \Gamma \), is a rational curve. This also is impossible, because \( S \) is of general type. Q.E.D. \( \square \)

From now onwards we shall suppose that \( C \in |2K - x - y| \) satisfies the requirements of Lemma 3 and Lemma 4 and write \( h_C = \mathcal{O}_C(x + y) \) for the hyperelliptic sheaf of \( C \).
Lemma 5. We have $\omega_C \cong h_C^{6}$.

Proof. Obvious, because $C$ is hyperelliptic. □

4 Proof of Theorem 1

As $P_3 = 7$ we have $\Phi = \Phi_{[3K]} : S \to \mathbb{P}^6$. We write $V = \Phi(S)$. $d = \deg V, m = \deg \Phi$ and note that, since $[3K]$ has no base points ([5]Th. A; see also [2]Th. 5.1) we have

$$dm = (3K)^2 = 18.$$ 

Also $d \geq 5$ because $V$ is not contained in any hyperplane and $V$ is not a curve, the latter because otherwise the general element of $[3K]$ would be decomposable in $d$ components, while the curves $D$ on $S$ with $KD \leq 1$ cannot move. This leads to the two cases $\deg \Phi = 2$ and $\deg \Phi = 3$.

Case I. $\deg \Phi = 2$.

Now $\Phi$ determines an involution $\sigma$ on $S$, which is everywhere regular because $S$ is of general type. We have

$$\sigma^* \mathcal{O}(K) \cong \mathcal{O}(K)$$

(this clearly holds for every surface of general type) and we remark that, $C$ being as in Section III, we also have

$$\sigma(C) = C.$$ 

In fact, $\sigma$ identifies pairs of points $x, y$ such that $\Phi(x) = \Phi(y)$; hence the above remark.

Lemma 6. We have $\mathcal{O}_C(K) \cong h_C^{12}$.

Proof. By Lemma 5 we have $\mathcal{O}_C(3K) = \omega_C \cong h_C^{6}$ therefore it is sufficient to prove that $\mathcal{O}_C(8K) \cong h_C^{16}$. In fact, since $[4K]$ is free
from base points, we can find a section \( s \in H^0(S, \mathcal{O}(4K)) \) with 16 zeros \( a_1, \ldots, a_{16} \) on \( C \). Then \( \sigma^*s \) has 16 zeros \( \sigma(a_1), \ldots, \sigma(a_{16}) \) on \( C \) and the section \( s \). \( \sigma^*s \) of \( \mathcal{O}(8K) \) has the zeros \( a_i, \sigma(a_i) \) on \( C \). It follows that the section \( s_\sigma s|_C \) of \( \mathcal{O}_C(8K) \) has divisor

\[
\text{div}(s \cdot \sigma^*s|_C) = \sum_{i=1}^{16} (a_i + \sigma(a_i)).
\]

Since each \( a_i + \sigma(a_i) \) is the divisor of a section of \( h_C \), the result follows. Q.E.D.

By Lemma 6, we have an exact sequence

\[
0 \to \mathcal{O}(-K) \to \mathcal{O}(K) \to h^{\otimes 2}_C \to 0
\]

which implies \( p_g = 3 \), a contradiction. This settles Case I.

Case II. \( \deg \Phi = 3 \).

Let \( A \) be a general point on \( C \) and let

\[
a + \overline{a} \in |h_C|.
\]

Then \( \Phi(a) = \Phi(\overline{a}) \) and, if \( a' \) is the third point with \( \Phi(a) = \Phi(\overline{a}) = \Phi(a') \) then \( a' \notin C \), as one immediately sees by considering \( \overline{a'} \) in case that \( a' \in C \). Consider \( \Phi(C) = N \). Now \( \Phi^{-1}(N) \) has a component \( N' = \text{locus} (a') \); \( \Phi|_{N'} : N' \to N \) is a birational map. However, points in \( N' = \text{locus} (a') \) are parametrized by \( |h_C| \cong \mathbb{P}^1 \), because \( a + \overline{a} \) determines \( a' \) uniquely; hence \( N' \) is rational and \( S \) contains a continuous family of rational curves, which is absurd. This settles Case II and completes the proof of Theorem 1.

References

1 Introduction

In the course of our study of vector bundles over a smooth projective curve we considered [5] a correspondence between the space of vector bundles of rank $n$ and degree $d$ on the one hand and that of vector bundles of rank $n$ and degree $(1-d)$ on the other. This is the geometric analogue of the Hecke Correspondence which is defined in the case of a curve defined over a finite field. Let $\xi$ be a line bundle on the curve $X$ and $U(n, \xi)$ (resp. $U(n, \xi^{-1}X)$) be the moduli space of vector bundles on $X$ of rank $n$ with determinant isomorphic to $\xi$ (resp. isomorphic to $\xi^{-1} \otimes L_x$, $x \in X$), $n \geq 2$. For a general vector bundle $E \in U(n, \xi)$, the subscheme corresponding to $E$ in $U(n, \xi^{-1}X)$ under this correspondence is isomorphic to the projective bundle $P(E^*)$. We call these subschemes of $U(n, \xi^{-1}X)$ good Hecke cycles. This identifies a suitable open subset of $U(n, \xi)$ with an open subset of the Hilbert scheme of $U(n, \xi^{-1}X)$. Results of this type were announced in [5§ 8] and are proved here in § 5 which can be read independently of the rest of the paper.

In the case $n = 2$, and $\xi$ is trivial we prove that the irreducible component (which we shall call for convenience the Hecke component) of the Hilbert scheme of $U(2, X)$ containing the good Hecke cycles is smooth and provides a non-singular model for $U(2, \xi)$. This is the main result of the paper (Theorem 8.14).

Now the Kummer variety associated to the Jacobian $J$ of $X$ is the set of non-stable (and even singular if the genus $g \geq 3$)
The possible elements of the Hecke component corresponding to points of the Kummer variety can be listed (§7) and they all turn out to be conic bundles over $X$. The fibre in the non-singular model over a non-nodal point $k$ of the Kummer variety is isomorphic to $\text{PH}^1(X, j^2) \times \text{PH}^1(X, j^{-2})$, where $j \in J$ lies above $k$, and the corresponding subschemes in $U(2, X)$ can be described as the union of two projective line bundles on $X$ corresponding to non-trivial extensions

\[ 0 \to j^{-1} \to E \to j \to 0 \]
\[ 0 \to j \to E' \to j^{-1} \to 0 \]

identified along the sections given by $j^{-1}$ and $j$ respectively. Over a node of the Kummer variety, the elements are trivial conic bundles contained in $X \times P(H^1(X, \mathcal{O}))$, (imbedded in $U(2, X)$), where $P(H^1(X, \mathcal{O}))$ is the thickening of $\text{PH}^1(X, \mathcal{O})$ corresponding to the universal quotient bundle $Q$ of $\text{PH}^1(X, \mathcal{O})$. (See §4.4 iii). Thus we get here not only conics contained in $\text{PH}^1(X, \mathcal{O})$ but also lines in it which are thickened within this $Q^*$-thickening. (The latter will be referred to as ‘outside thickenings’). It is proved that the Hilbert scheme is itself smooth at all these points except at 1) a pair of intersecting lines in $\text{PH}^1(X, \mathcal{O})$, 2) double lines contained schematically in $\text{PH}^1(X, \mathcal{O})$ (§8). At points of the above type another component of the Hilbert scheme hits the Hecke component. We show that there is a natural morphism of the union of these two components into the Jacobian of $X$, which is constant on the Hecke component. (This morphism should be thought of as playing the role of the Weil morphism into the intermediary Jacobian). By studying the differential of this morphism we show that the Hecke component is smooth also at these points. (See Lemmas 8.10, 8.11).

The conics contained schematically in $\text{PH}^1(X, \mathcal{O})$ is a $\mathbb{P}^5$ bundle over the Grassmannian of planes in $\text{PH}^1(X, \mathcal{O})$. It will be shown in a later paper that the non-singular model considered above can be blown down along these fibrations (one for each
node) to another non-singular model.

It turns out that all the subschemes described above consist of bundles which are non-trivial extensions of line bundles of a particular kind. Such (triangular) bundles are parametrised by a projective bundle over $X \times J$. We have a morphism from this space into $U(2, X)$, which may also be looked upon as a family $\{P(D_j)\}_{j \in J}$ of smooth subvarieties of $U(2, X)$ parametrised by $J$, where each $P(D_j)$ is a projective bundle over $X$ of dimension $(g - 1)$. One of the essential points in the proof is to study the first and second order differentials of this morphism and in particular to compute its Hessian at the critical points (§ 6). The necessary preliminaries for this are discussed in § 2. This study is necessary to prove the non-singularity of the Hilbert scheme at a point given by an ‘outside thickening’. For this we need information about the conormal sheaf of the thickening $X \times PH^1(X, \mathcal{O})_t$ of $X \times PH^1(X, \mathcal{O})$ in $U(2, X)$. Now this thickening is a special case of thickenings which arise in the study of a family of smooth subvarieties (in our case, the family $j \mapsto P(D_j)$ mentioned above). In this situation the conormal sheaf of the thickened scheme can be described in terms of the Hessian (see Lemma 3.7 and Remark 3.9).

A different approach for the desingularisation of $U(2, \xi)$ has been found by C.S. Seshadri [10].

**Notation.** All schemes will be of finite type over an algebraically closed field $k$ of characteristic $\neq 2$. From § 5 on, $X$ will denote a smooth projective curve of genus $g \geq 2$. If $S$ is a subscheme of Pic $X$, $U(n, S)$ will denote the subscheme of the moduli scheme $U(n, d)$ of $S$-equivalence classes of semistable vector bundles of rank $n$ of degree $d$ obtained as the inverse image of $S$ by the morphism $det : U(n, d) \to \text{Pic}$. The Jacobian of $X$ will be denoted $J$. If $E$ is a family of semistable vector bundles over $X$, then there is a canonical morphisms $\theta_E$ of the parameter space into the moduli space.

If $X$ is a subscheme of $Y$, we denote by $\mathcal{N}_{X,Y}$ the conormal
sheaf of $X$ in $Y$. In good cases, e.g. when $X$ is regularly imbedded in $Y$, the sheaf $\tilde{N}_{X,Y}$ is locally free and its dual is the normal bundle denoted $N_{X,Y}$ so that in that case, $\tilde{N}_{X,Y} = N_{X,Y}^*$. If $\pi : X \to Y$ is a smooth morphism, we denote by $T_\pi$, the tangent bundle along the fibres of $\pi$. Its dual is sometimes denoted by $\Omega^1_\pi$ as well. If $x$ is a (closed) point of $X$, the tangent space at $x$ is denoted $T_x$.

If $D$ is a Cartier divisor in a scheme $X$, then $L_D$ will denote the line bundle defined by it. If $L$ is a line bundle generically generated by sections, then the quotient sheaf of $H^0(X, L)_X^*$ by the subsheaf $L^*$ will be called the quotient sheaf of the linear system defined by $L$. If $\mathcal{F}$ is a coherent sheaf on a closed subscheme $i : Y \to X$, the sheaf $i_*(\mathcal{F})$ will be denoted by $\tilde{\mathcal{F}}$.

If $\pi : X \to Y$ is a projective morphism with a relatively ample sheaf then $\text{Hilb}(X, Y, P)$ will denote the relative Hilbert scheme over $Y$ with Hilbert polynomial $P$. If $Y = \text{Spec} \, k$, we simply write $\text{Hilb}(X, P)$.

The projections from $X \times Y \times Z$ to the component schemes will be denoted $p_1$, $p_2$, $p_3$, $p_{12}$, $p_{23}$, $p_{13}$. When we are dealing with closed subschemes or closed imbeddings we usually omit the word “closed”.

# 2 Deformations of Principal bundles

We wish to recall certain facts concerning deformations of locally trivial principal $G$-bundles, where $G$ is an algebraic group, and in particular study the second order infinitesimal deformations of such bundles.

**Definition 2.1.** Let $P$ be a principal $G$-bundle on $X$ and $(S, s_0)$ a pointed scheme. A deformation of $P$ parametrised by $S$ is a principal $G$-bundle $Q$ over $X \times S$, and an ismorphism $\Psi$ of $Q|X \times s_0$ with $P$. Two deformations $Q_1$, $Q_2$ are said to be equivalent if for every $s \in S$, there exists a neighbourhood $U$ and an isomorphism
\[ f : Q_1 | X \times U \to Q_2 | X \times U \text{ such that the diagram} \]

\[ \begin{array}{ccc}
Q_1 & \xrightarrow{\Psi_1} & P \\
\downarrow f|X \times s_0 & & \downarrow \Psi_2 \\
Q_2
\end{array} \]

commutes if \( s_0 \in U' \).

**Remark 2.2.**  
(i) If the only automorphisms of \( P \) are given by morphisms of \( X \) into the centre of \( G \), then it is clear that the equivalence class of a deformation \( Q \) of \( P \) is independent of \( \Psi \).

(ii) If \( P \) is a principal \( G \)-bundle on \( X \), then we have obviously the deformation functor \( \delta_P \) on the category of Artinian local algebras which associates to \( A \), the equivalence class deformations of \( P \) parametrised by \( A \). This functor can be seen to satisfy the conditions \( H_1 \) and \( H_2 \) of Schlessinger [7, Theorem 2.11]. If \( X \) is proper \( k \), it satisfies \( H_3 \) as well. Moreover, if \( P \) is such that \( H^0(X, Z_X) \to H^0(X, \text{Ad} P) \) is an isomorphism, where \( Z \) denotes the centre of the Lie algebra of \( G \), then \( \delta_P \) also satisfies \( H_4 \) and hence is prorepresentable. We proceed to describe this functor a little more explicitly.

**Proposition 2.3.** Let \( S \) be an Artinian local algebra, and \( s_0 \) its closed point. Then \( \delta_P(S) \) is canonically bijective with the set \( H^1(X, N) \) where \( N \) is the sheaf associated to the group scheme \( N = \ker p_*p^*G(\overline{P}) \to G(\overline{P}) \), where this map is given by restriction to \( X \times s_0 \), \( G(P) \) is the group scheme \( \text{Aut} \ P \) and \( p : X \times S \to X \) is the projection.

**Proof.** The set of principal \( G \)-bundles on \( X \times S \) are in (1, 1) correspondence with the set \( H^1(X \times S, p^*G(P)) \approx H^1(X, p_*p^*G(P)) \).
Thus any deformation of $P$ gives rise to an element in $H^1(X, \pi_* \pi^* G(P))$ which is in the ‘kernel’ of $H^1(X, \pi_* \pi^* G(P)) \to H^1(X, G(P))$. But the prescription of $\Psi$ allows one to describe the deformation as a 1-cocycle for $\pi_* \pi^* G(P)$ and a 0-cochain for $G(P)$ of which its image in $G(P)$ is the coboundary. This proves the assertion. □

**Proposition 2.4.** Let $(A, m)$ be an Artinian local algebra with $m^2 = 0$ (resp. $m^3 = 0$). Then the group scheme $N$ of 2.3 is isomorphic to the vector bundle $\text{Ad} P \otimes m$ (resp. the group scheme $\text{Ad} P \otimes m$, the group structure being defined by $(X, Y) \to X + Y + \frac{1}{2}[X, Y]$).

**Proof.** The exponential map yields a bijection of $\text{Ad} P \times m$ onto $N$, and the transfer of the group structure on $N$ to $\text{Ad} P \otimes m$ is as given above, by virtue of the Campbell-Hausdorff formula [9, SGA 3, Expose VII, 3.1]. □

**Remark 2.5.** If the field $k$ is of characteristic 0, we have an obvious generalisation of 2.4 to all Artinian local algebras using the Campbell-Hausdorff formula.

**Example 2.6.** Let $A$ be the algebra $k[\epsilon_1, \epsilon_2]/(\epsilon_1^2, \epsilon_2^2)$. Then $H^1(X, \text{Ad} P \otimes m)$ can be described with respect to a suitable open covering $(U_i)$ of $X$ as follows. Any 1-cochain can be described by $f_{ij} \epsilon_1 + g_{ij} \epsilon_2 + h_{ij} \epsilon_1 \epsilon_2$ where $f_{ij}, g_{ij}, h_{ij}$ belong to $H^0(U_i \cap U_j, \text{Ad} P)$. The cocycle condition with respect to the above group structure on $\text{Ad} P \otimes m$ is that, for every $i, j, k$, we have

\[
 f_{ik} \epsilon_1 + g_{ik} \epsilon_2 + h_{ik} \epsilon_1 \epsilon_2 = (f_{ij} \epsilon_1 + g_{ij} \epsilon_2 + h_{ij} \epsilon_1 \epsilon_2)(f_{jk} \epsilon_1 + g_{jk} \epsilon_2 + h_{jk} \epsilon_1 \epsilon_2)
\]

\[
 = (f_{ij} + f_{jk}) \epsilon_1 + (g_{ij} + g_{jk}) \epsilon_2 + \frac{1}{2}([f_{ij}, g_{jk}] + [g_{ij}, f_{jk}]) + h_{ij} + h_{jk} \epsilon_1 \epsilon_2
\]

or, what is the same, $f_{ij}, g_{ij}$ are 1-cocycles of $\text{Ad} P$, and $h_{ij}$ satisfies

\[
 h_{ij} + h_{jk} = h_{ik} - \frac{1}{2}([f_{ij}, g_{jk}] + [g_{ij}, f_{jk}]). \tag{2.7}
\]

On the other hand, two cocycles $(f_{ij}, g_{ij}, h_{ij})$ and $(f'_{ij}, g'_{ij}, h'_{ij})$ are
cohomologous if and only if there exist sections \((a_i, b_i, c_i)\) over \(U_i\) of \(\text{ad } P\) with

\[
(f_{ji} \epsilon_1 + g_{ij} \epsilon_2 + h_{ij} \epsilon_1 \epsilon_2)(a_j \epsilon_1 + b_j \epsilon_2 + c_j \epsilon_1 \epsilon_2) = (a_i \epsilon_1 + b_i \epsilon_2 + c_i \epsilon_1 \epsilon_2) \times (f_{ij}' \epsilon_1 + g_{ij}' \epsilon_2 + h_{ij}' \epsilon_1 \epsilon_2);
\]

namely, \(f_{ij}' - f_{ij}\) is the coboundary of \((a_i)\) in \(\text{Ad } P\), \(g_{ij}' - g_{ij}\) is the coboundary of \((b_i)\), and

\[
h_{ij}' - h_{ij} = c_j - c_i + \frac{1}{2}([f_{ij}, b_j] + [g_{ij}, a_j] - [b_i, f_{ij}'] - [a_i, g_{ij}']) \tag{2.8}
\]

### 2.9 Hessian.

Let \(f\) be a morphism of a smooth scheme \(X\) into a scheme \(Y\) and \(df : T_x \to T_y, y = f(x)\) be its differential. Then the Hessian \(h(f)\) of \(f\) is defined to be a map \(\ker df \otimes T_x \to \coker df\). It is more convenient to define the dual map \(\bar{h}(f) : \ker(\bar{d}f) \otimes T_x \to \coker \bar{d}f\).

Let \((\mathcal{O}_x, \mathfrak{m}_x), (\mathcal{O}_y, \mathfrak{m}_y)\) be the local rings at \(x, y\). If \(a \in \mathfrak{m}_y\), with \(a \circ f \in \mathfrak{m}_x^2\) and \(t \in T_x\), then we get an element of \(T_y\), by contracting with \(t\) the element in \(S^2(\mathfrak{m}_x/\mathfrak{m}_x^2) = \mathfrak{m}_x^2/\mathfrak{m}_x^3\) given rise to by \(a \circ f\). Its image in \(\coker df\) depends only on the class of \(a\) modulo \(\mathfrak{m}_y^2\) and is defined to be \(\bar{h}(f)(a, t)\).

### 2.10 Functorial Description of Hessian.

In terms of \(A\)-valued points, the Hessian can be described as follows. Consider the ring

\[
A = k[\epsilon_1, \epsilon_2]/(\epsilon_1^2, \epsilon_2^2)
\]

and the quotient rings \(B_1, B_2\) and \(C\) given by the ideals \((\epsilon_2), (\epsilon_1)\) and \((\epsilon_1 \epsilon_2)\). Giving vectors \(a, t\) in \(\ker df\) and \(T_x\) respectively is the same as giving a \(C\)-valued point \(p\) of \(X\) at \(x\) such that the corresponding \(B_1\)-valued point is mapped by \(f\) on the 0-vector at \(y\). Let \(q\) be an \(A\)-valued point extending \(p\); there exists one such since \(X\) is smooth. By assumption, the image \(f(q)\) actually
yields a \((k + k\epsilon_2 + k\epsilon_1\epsilon_2)\)-valued point at \(y \in Y\). By restriction to \(\text{Spec}(k + k\epsilon_1\epsilon_2)\), we get a vector at \(y\). Its image modulo Image \((df)\) is independent of the extension \(q\) of \(p\) and gives \(h(f)(a, t)\).

**Remark 2.11.** The above definition of Hessian in terms of \(A\)-valued points enables one to define the Hessian of a morphism of a smooth, prorepresentable functor on the category of Artinian local algebras into another prorepresentable functor. In particular, if \(P\) is a principal \(G\)-bundle with \(H^2(X, \text{Ad} P) = 0\), then it is easy to check that the functor \(\delta_P\) defined in 2.2, (ii) is smooth. Hence if \(P\) satisfies in addition the conditions of 2.2, (ii), then for any homomorphism of \(G\) into another algebraic group \(H\), the notion of Hessian of the morphism \(\delta_P \to \delta_Q\) makes sense, where \(Q\) is the principal \(H\)-bundle associated to \(P\). We proceed to compute this in the case when \(G \subset H\).

**Proposition 2.12.**  
(i) Let \(P\) be a principal \(G\)-bundle on a scheme \(X\), proper over \(k\). For any homomorphism \(G \to H\), the induced morphism \(e_{G,H} : \delta_P \to \delta_Q\) of the deformation functors has as differential, the natural map \(H^1(X, \text{Ad} P) \to H^1(X, \text{Ad} Q)\), where \(Q\) is the principal \(H\)-bundle associated to \(P\).

(ii) If \(H^2(X, \text{Ad} P) = 0\) and \(G \subset H\), then the cokernel of \(de_{G,H}\) is canonically isomorphic to \(H^1(X, E)\) where \(E\) is the vector bundle associated to \(P\) for the linear isotropy action of \(G\) on the tangent space at \(e\) of \(H/G\).

(iii) Assume that \(Q\) (and hence \(P\)) satisfies the condition in 2.2, (ii). Under the identification in (ii), the Hessian of \(e_{G,H}\) can be described as follows. Let \(t_1 \in \ker de_{G,H}\) and \(t_2 \in H^1(X, \text{Ad} P)\). Then \(t_1\) is in the image under the boundary homomorphism of an element \(s_1 \in H^0(X, E)\) associated to the exact sequence

\[
0 \to \text{Ad} P \to \text{Ad} Q \to E \to 0.
\]
Then \( h(t_1, t_2) = [s_1, t_2] \), where the bracket is the cup product associated to the natural action of \( \text{Ad} P \) on \( E \).

**Proof.** (i) is obvious from 2.4.

(ii) is a trivial consequence of (i) and the cohomology sequence of \( 0 \to \text{Ad} P \to \text{Ad} Q \to E \to 0 \).

(iii) We will use the notation of 2.10. By the description of the Hessian given there and of the functors \( \delta_P, \delta_Q \) given in 2.4, \( h(t_1, t_2) \) is obtained as follows. The vectors \( t_1, t_2 \) give an element of \( H^1(X, \text{Ad} P \otimes \mathfrak{m}/(\epsilon_1, \epsilon_2)) \) where \( \mathfrak{m} \) is the maximal ideal of \( A \). This is the image of an element in \( H^1(X, \text{Ad} P \otimes \mathfrak{m}) \), the group structure in \( \text{Ad} P \otimes \mathfrak{m} \) being given in 2.4. Its image in \( H^1(X, \text{Ad} Q \otimes \mathfrak{m}) \) goes to zero in \( H^1(X, \text{Ad} Q \otimes \mathfrak{m}/(\epsilon_2)) \) and hence comes from an element in \( H^1(X, \text{Ad} Q \otimes (\epsilon_2)) \). The image of this element in \( H^1(X, E \otimes (\epsilon_2)/(k\epsilon_2)) \) is \( h(t_1, t_2) \). In terms of cocycles for a suitable covering \((U_i)\) of \( X \) (as in 2.6) this means the following. Let \( f_{ij}, g_{ij} \) be cocycles representing \( t_1, t_2 \), in \( H^1(X, \text{Ad} P) \). Then there exists \( h_{ij} \in H^0(U_i \cap U_j, \text{Ad} P) \) such that \((f_{ij}, g_{ij}, h_{ij})\) satisfy 2.7. Reading these as sections over \( U_i \cap U_j \) of \( \text{Ad} Q \), we get a corresponding element of \( H^1(X, \text{Ad} Q \otimes \mathfrak{m}) \). We are given that \( f_{ij} \) is a coboundary for \( \text{Ad} Q \), namely, there exist \( \lambda_i \in H^0(U_i, \text{Ad} Q) \) with \( f_{ij} = \lambda_j - \lambda_i \). Then the cocycle \((f_{ij}, g_{ij}, h_{ij})\) is cohomologous by \( 2.8 \) to \((0, g_{ij}, h_{ij} + \frac{1}{2}([\lambda_i, g_{ij}] - [g_{ij}, \lambda_j]), \text{taking } (a_i, b_i, c_i) = (\lambda_i, 0, 0) \). Thus the element in \( H^1(X, \text{Ad} Q \otimes (k\epsilon_2 + k\epsilon_1\epsilon_2)) \) is given by the cocycle \( g_{ij}\epsilon_2 + h_{ij} + \frac{1}{2}([\lambda_1 g_{ij}] - [g_{ij}, \lambda_j])\epsilon_1\epsilon_2 \). Finally, the Hessian \( h(t_1, t_2) \) is given by the cocycle \( \frac{1}{2}([\lambda_i g_{ij}] - [g_{ij}, \lambda_j]) \) of \( E \), since \( h_{ij} \) is a section of \( \text{Ad} P \). Notice that since \( \lambda_i - \lambda_j \) is a section of \( \text{Ad} P, \lambda_i = \lambda_j \) as sections of \( E \) on \( U_i \cap U_j \) and hence \((\lambda_i)\) determines a section \( \lambda \) of \( E \). Clearly \( \lambda \) maps on \((f_{ij})\) under the boundary homomorphism and the cocycle \( \frac{1}{2}([\lambda, g_{ij}] - [g_{ij}, \lambda]) = [\lambda, g_{ij}] \) represents the cup product of \( \lambda \) and the class of \( g_{ij} \) as was to be proved.
Remarks 2.13. (i) We will apply Proposition 2.12 to the case when $G$ is $2 \times 2$ triangular (Borel) subgroup of $H = GL(2, k)$, and $P$ is a principal bundle over the curve $X$. Then $P$ is described by an exact sequence

$$0 \rightarrow L_1 \rightarrow W \rightarrow L_2 \rightarrow 0,$$

where $L_1$ and $L_2$ are line bundles. If $W$ is simple, then the conditions in Prop. 2.12 are satisfied. The bundle $\text{Ad} P$ is the bundle $\Delta(W)$ of endomorphisms of $W$ leaving $L_1$ invariant, $\text{Ad} Q = \text{End} W$, and the vector bundle $E$ can be identified with $\text{Hom}(L_1, L_2)$. Moreover, the bundle $\text{Ad} P$ consisting of endomorphisms of trace 0 is isomorphic to $\text{Hom}(L_2, W)$. In particular, we have a map $\eta$ of $\text{Ad} P$ onto the sheaf $\mathcal{O}_X$, obtained by composing with the map $W \rightarrow L_2$. With these identifications, the action of $\text{Ad} P$ on $E$ is simply multiplication by its image in $\mathcal{O}$. Thus if $t_1 \in \ker H^1(X, \text{Ad} P) \rightarrow H^1(X, \text{Ad} Q)$, and $t_2 \in H^1(X, \text{Ad} P)$, then $h(t_1, t_2) \in H^1(X, E)$ is the cup product of $\eta t_2 \in H^1(X, \mathcal{O})$ and the element $s_1 \in H^0(X, \text{Hom}(L_1, L_2))$ of which $t_1$ is the image. In other words, $h(t_1, t_2)$ is simply the image of $\eta t_2 \in H^1(X, \mathcal{O})$ in $H^1(X, \text{Hom}(L_1, L_2))$ by the map $\mathcal{O} \rightarrow \text{Hom}(L_1, L_2)$ given by $t_1$.

(ii) If global fine moduli schemes for principal $G$ and $H$ bundles exist, then clearly Proposition 2.12 enables one to compute the Hessian of the morphism $e_{G,H}$ induced on the moduli schemes by extension of structure group.

3 Thickenings

Let $X$ be a scheme and $\mathcal{F}$ a coherent sheaf of $\mathcal{O}$-Modules on $X$. Let $\varphi : \mathcal{F} \rightarrow \Omega^1_X$ be a surjective $\mathcal{O}_X$-homomorphism of $\mathcal{O}_X$-Modules. Then one can define a ring structure on the subsheaf of
\( \mathcal{O} \oplus \mathcal{F} \) consisting of \( \{(f, x) : df = \varphi x\} \). This is a subsheaf \( \mathcal{O}_\varphi \) of rings if we consider \( \mathcal{O} \oplus \mathcal{F} \) as an \( \mathcal{O} \)-Algebra with \( \mathcal{F}^2 = 0 \).

**Lemma 3.1.** \((X, \mathcal{O}_\varphi)\) is a scheme.

*Proof.* If \( X = \text{Spec} A \) is affine, then \((X, \mathcal{O}_\varphi) \simeq \text{Spec}(M + \varphi \Omega^1)\) where \( \widetilde{M} = \mathcal{F} \). This shows in general that \((X, \mathcal{O}_\varphi)\) is a prescheme and since \((X, \mathcal{O}_\varphi)_{\text{red}} = (X, \mathcal{O})_{\text{red}}\) is a scheme, the lemma is proved. \( \square \)

If \( I = \ker \varphi \), then we have an exact sequence of \( \mathcal{O}_\varphi \)-Modules (\( I \) being considered as an \( \mathcal{O}_\varphi \)-Module)

\[
0 \to I \to \mathcal{O}_\varphi \to \mathcal{O} \to 0.
\]

**Lemma 3.2.** Let \( X \) be a smooth irreducible scheme. The scheme \( X_\varphi = (X, \mathcal{O}_\varphi) \) is Cohen-Macaulay if and only if \( I \) is a locally free \( \mathcal{O}_X \)-Module. In this case, the dualising sheaf of \( X_\varphi \) restricts to \( X \) as \( \text{Hom}(I, \omega_X) \). Moreover, \( X_\varphi \) is a local complete intersection if and only if \( I \) is locally free of rank 1 or 0.

*Proof.* The problem being local, we may assume that \( X = \text{Spec} A \) and \( X_\varphi = \text{Spec} A_\varphi \), and since \( \Omega^1_X \) is locally free, we may also assume that \( A_\varphi = A \oplus I \), with \( I^2 = 0 \). In the local case, an \( A \)-sequence is an \( A_\varphi \)-sequence if and only if it is an \( I \)-sequence as well. Hence the first assertion. Now, if \( I \) is free, then \( A_\varphi = A \otimes (k \oplus V) \) with \( V^2 = 0 \), where \( V \) is a finite dimensional \( k \)-vector space. Thus, our assertion on the dualising sheaf needs only to be proved when \( X_\varphi = \text{Spec}(k \otimes V) \). In this case, the dualising sheaf is seen to be actually \( k \oplus V^* \), in which \( V \) operates trivially on \( k \) and by duality on \( V^* \). To prove the last assertion, we note that if \( A_\varphi \) is a complete intersection, then so is \( k \oplus V \), and hence \( k \oplus V^* \) is free over \( k \oplus V \). This clearly implies that \( \dim V \leq 1 \), while, on the other hand, it is obvious that \( \dim V = 1 \) implies \( k \oplus V \) is a complete intersection. \( \square \)
Remark 3.3. Let $X$ be a smooth subscheme of a scheme $Y$. Then we have an exact sequence

$$0 \to \tilde{N}_{X,Y} \to \Omega^1_Y|_X \to \Omega^1_X \to 0.$$ 

If $\tilde{N}_{X,Y} \to I$ is an $\mathcal{O}_X$-homomorphism into an $\mathcal{O}_X$-Module $I$, then by the push-out construction, we obtain a sheaf $\mathcal{F}$ and a surjective homomorphism $\varphi : \mathcal{F} \to \Omega^1_X$. In particular, this gives rise to the scheme $X_\varphi$. Moreover, there is a natural morphism $X_\varphi \to Y$ making the diagram

$$
\begin{array}{ccc}
X_\varphi & \xrightarrow{\varphi} & Y \\
\downarrow & & \downarrow \\
X & \rightarrow & Y
\end{array}
$$

commutative. It is easy to see that this morphism $X_\varphi \to Y$ is a closed immersion if and only if $\tilde{N}_{X,Y} \to I$ is surjective. (In this case, the thickened subscheme $X_\varphi$ of $Y$ will be denoted by $X_I$). In other words, all the thickenings of $X$ ‘inside’ $Y$ are given by Quot $\tilde{N}_{X,Y}$. In the case when $Y = Z_\psi$, with $Z$ smooth and $\psi$ a surjective homomorphism $\mathcal{F} \to \Omega^1_Z$, then $\tilde{N}_{X,Y}$ is the kernel of the map $\mathcal{F}|_X \to \Omega^1_X$, obtained as the composite of $\psi|X$ and the map $\Omega^1_Z|_X \to \Omega^1_X$.

Lemma 3.4. Let $X$ be a smooth subscheme of a smooth scheme $Z$, and let $Q$ be a locally free quotient of $N^*_X,Z$. If $\eta : N^*_X,Z \to Q$ is the canonical map, then the restriction of $N_{X,Z}^*$ to $X$ fits in the exact sequence

$$0 \to S^2(Q) \to N_{X,Z}^*|X \to \ker \eta \to 0.$$

Proof: Let $I$ (resp. $J$) be the ideal sheaf of $X$ (resp. $X_Q$) in $Z$. We may choose local parameters $(x_1, \ldots, x_l, y_1, \ldots, y_m, z_1, \ldots, z_n)$ at a point of $X$ so that

$I = \{x_1, \ldots, x_l, y_1, \ldots, y_m\}$ and $J = \{x_i, x_j, y_1, \ldots, y_n\}$, $i, j = 1, \ldots l$. 

From this it is clear that $I^2/IJ$ is locally free and the natural map $S^2(Q) = S^2(I/J) \to I^2/IJ$ is an isomorphism. On the other hand $N_{X,Q,Z}|X \cong J|IJ$ fits in the exact sequence

$$0 \to I^2/IJ \to J|IJ \to J/I^2 \to 0.$$  

Now $N_{X,Z}^* \cong I/I^2$ and the map $\eta$ is the natural projection $I/I^2 \to I/J$ and hence ker $\eta = J/I^2$, proving the lemma. □

The following functorial remark on the extension 3.4 is an immediate consequence of the definition.

**Lemma 3.5.** If $X$ is a smooth subscheme of a smooth scheme $Z$ and $\eta_1 : N_{X,Z}^* \to Q_1$, $\zeta : Q_1 \to Q_2$ are surjections, then the extensions corresponding to $X_{Q_1}$ and $X_{Q_2}$ fit in a commutative diagram

$$0 \to S^2(Q_1) \to N_{X_{Q_1},Z}|X \to \ker \eta_1 \to 0$$

$$0 \to S^2(Q_2) \to N_{X_{Q_2},Z}|X \to \ker \zeta \circ \eta_1 \to 0$$

**Remark 3.6.** We will not determine the extension involved in 3.4 in the following situation. Let $\varphi : Y \to Z$ be a morphism of smooth schemes and $X$ a smooth subscheme of $Y$ on which $\varphi$ is an imbedding. Then the Hessian (see §2.9) of the map $\varphi$ along $X$ goes down to a map $K \otimes N_{X,Y} \to \text{Coker } d\varphi$ where $K = \ker d\varphi$. Now $d\varphi$ induces a map $N_{X,Y} \to N_{X,Z}$ and let $Q$ be the image of its transpose. We wish to consider the thickening of $X$ in $Z$ given by $\eta : N_{X,Z}^* \to Q$. It is easily seen that this thickening is in fact the schematic image (by $\varphi$) of the total normal thickening of $X$ in $Y$.

**Lemma 3.7.** In the situation of 3.6 we further assume that $K = \ker d\varphi$ has rank 1 at all points of $X$. Then the extension in Lemma 3.4 is the pull back by means of the transpose of the Hessian : $\ker \eta \to K^* \otimes N_{X,Y}^*$ of the exact sequence

$$0 \to S^2(Q) \to S^2(N_{X,Y}^*) \to K^* \otimes N_{X,Y}^* \to 0$$
obtained by symmetrising the exact sequence

\[ 0 \to Q \to N_{X,Y}^* \to K^* \to 0. \]

**Proof.** We use the notation of 3.4. Let \( I' \) be the ideal of \( X \) in \( Y \). Then notice that \( f \in I \Rightarrow f \circ \varphi \in I' \) and \( f \in J \Rightarrow f \circ \varphi \in I'^2 \). Hence we have a map \( J/IJ \to I'/I'^3 = S^2(N_{X,Y}^*) \) induced by \( \varphi \). The resulting map \( J/I'^2 = (N/Q)^* \to K^* \otimes N_{X,Y}^* \) is easily seen to be the transpose of the Hessian. \( \square \)

Putting together Lemmas 3.5 and 3.7 we obtain

**Proposition 3.8.** In the situation of 3.7, let \( L \) be a locally free quotient of \( Q \). Then the pullback of the extension 3.4 for \( X_L \) by the inclusion \( \ker \eta \to \ker(N_{X,Z}^* \to L) \) is isomorphic to the pullback of the sequence

\[ 0 \to S^2(L) \to S^2(E) \to K^* \otimes E \to 0 \]

by the map \( K^* \otimes N_{X,Y}^* \to K^* \otimes E \), where this latter extension is obtained by symmetrising the sequence

\[ 0 \to L \to E \to K^* \to 0, \]

\( E \) being the push-out \( N_{X,Y}^* \mid_{Q} L \).

**Proof.** From Lemma 3.5 we obtain the commutative diagram

\[
\begin{array}{cccccc}
0 & \to & S^2(L) & \to & \tilde{N}_{X,L} \mid X & \to \ker(N_{X,Z}^* \to L) & \to 0 \\
& & \uparrow & & \uparrow & & \\
0 & \to & S^2(Q) & \to & \tilde{N}_{X,Q} \mid X & \to \ker \eta & \to 0
\end{array}
\]

This shows that the required pullback is the push-out of the sequence

\[ 0 \to S^2(Q) \to \tilde{N}_{X,Q} \mid X \to \ker \eta \to 0 \]
by the map $S^2(Q) \rightarrow S^2(L)$. Now the proposition follows from the description of this sequence in Lemma 3.7 and the obvious commutative diagram

$$
\begin{array}{cccccc}
0 & \rightarrow & S^2(L) & \rightarrow & S^2(E) & \rightarrow & K^* \otimes E & \rightarrow & 0 \\
& & \uparrow & & \uparrow & & \downarrow & & \\
0 & \rightarrow & S^2(Q) & \rightarrow & S^2(N_{X,Y}^*) & \rightarrow & K^* \otimes N_{X,Y}^* & \rightarrow & 0 \\
\end{array}
$$

\[ \square \]

\textbf{Remark 3.9.} In our applications, we will be only considering the special case of (3.6), where we have $\psi : Y \rightarrow T$ is a proper smooth morphism and $\varphi$ realises the fibres $\{X\}$ of $\psi$ as a family of smooth subschemes of $Z$.

\section*{4 Conics}

\textbf{Definition 4.1.} A scheme $C$ together with a very ample line bundle $h$ is said to be a conic if its Hilbert polynomial is $(2m + 1)$. \textit{A scheme $C$ over $T$ is said to be a conic over $T$ if with respect to a line bundle on $C$ its fibres are conics and the morphism $C \rightarrow T$ is faithfully flat.}

We will show in 4.2 and 4.3 that this coincides with the usual notion of a conic.

\textbf{Lemma 4.2.} If $C$ is a reduced scheme and $h$ a very ample line bundle on $C$ with Hilbert polynomial of the form $2m + \delta$, $\delta \leq 1$, then $\delta = 1$, $C$ is isomorphic to a (reduced) conic in $P^2$, and $h$ is the restriction to $C$ of the hyperplane bundle on $P^2$.

\textbf{Proof.} It is obvious that we may assume without loss of generality that $C$ is pure 1-dimensional. Clearly then, either $C$ is irreducible, or $C$ has two components $C_1$, $C_2$ with Hilbert polynomials $m + d_1$, $m + d_2$ with $d_1 + d_2 - l = \delta$, where $l$ is the length
of the intersection $C_1 \cap C_2$. In the former case the normalisation of $C$ has to be rational; for, otherwise, a linear system of degree 2 is at most one dimensional and cannot imbed $C$. Moreover, if $C$ is not normal, the linear system of $h$ on $C$ will have dimension $\leq 1$, which cannot imbed $C$. Thus if $C$ is irreducible, it must be isomorphic to $\mathbb{P}^1$ and the bundle $h$ is the square of the hyperplane bundle on $\mathbb{P}^1$. In the case when $C$ has two components $C_1$ and $C_2$, we conclude as above that $C_1$, $C_2$ are both isomorphic to $\mathbb{P}^1$ and $h$ restricts to each of these as the hyperplane bundle. Thus we have $d_1 = d_2 = 1$. From the nature of the Hilbert polynomial, it is clear that $C_1$ and $C_2$ intersect. But $\dim H^0(C, h) = 4 - 1 \geq 3$ since $h$ is very ample. Hence $l = 1$, i.e. $C$ is a pair of intersection lines in $\mathbb{P}^2$. □

**Lemma 4.3.** Let $C$ be a nonreduced scheme and $h$ an ample bundle on $C$ with Hilbert polynomial of the form $2m + \delta$, $\delta \leq 1$. If $h|C_{\text{red}}$ is very ample, then $C$ contains a unique subscheme $C'$ which is obtained by thickening $\mathbb{P}^1$ by a line bundle $L$ of degree $\leq -1$. If degree $L = -1$, then $L$ must be the dual of the hyperplane bundle and $C = C'$. In otherwords, $C$ is isomorphic to the total thickening of a line in $\mathbb{P}^2$. In particular, a nonreduced conic (in the sense of 4.1) is such a thickened line.

Proof. Clearly, we may assume $C$ has no zero-dimensional components. Consider the exact sequence

$$0 \to I \to \mathcal{O} \to \mathcal{O}_{\text{red}} \to 0$$

on $C$, where $I$ is the ideal of nilpotents in $\mathcal{O}$. If $I$ has finite support, the Hilbert polynomial of $\mathcal{O}_{\text{red}}$ is of the same form and hence by 4.2 must be $2m + 1$. This shows that $\mathcal{O} = \mathcal{O}_{\text{red}}$, contrary to assumption. Thus the support of $I$ is 1-dimensional. It follows that the Hilbert polynomials of $I$ and $\mathcal{O}_{\text{red}}$ are of the form $m + d_1$, $m + d_2$. Since $h|C_{\text{red}}$ is very ample, we conclude as in 4.2 that $C_{\text{red}}$ is isomorphic to $\mathbb{P}^1$, and $h$ restricts to $\mathbb{P}^1$ as the hyperplane bundle. Now consider the filtration

$$\mathcal{O} \supset I \supset I^2 \ldots \supset I^n = (0).$$
Since the Hilbert polynomial $m + d_1$ of $I$ is the sum of the Hilbert polynomials of the sheaves $I^k/I^{k+1}$ on $\mathbb{P}^1$, it follows that $rk I/I^2 = 1$ and $I^k/I^{k+1}$ are all torsion sheaves for $k \geq 2$. If $L$ is the line bundle on $\mathbb{P}^1$ obtained as the free quotient of $I/I^2$, we get an $L$-thickening $C'$ of $\mathbb{P}^1$ as a subscheme of $C$. Since now the Hilbert polynomial of $\mathcal{O}_{\text{red}}$ is $m + 1$, the Hilbert polynomial of $I$ is $m + \delta - 1$ and hence that of $L$ is $m + d$, with $d \leq 0$. In particular, the degree of $L \geq -1$. If now $\deg L = -1$, then $L$ is the dual of the hyperplane bundle on $\mathbb{P}^1$ whose Hilbert polynomial is $m$, and hence that of $C'$ is $2m + 1$. This proves that $\delta = 1$ and $C = C'$. It is clear that the $L$-thickening of $\mathbb{P}^1$ is the normal thickening of a line in $\mathbb{P}^2$. Finally, if $h$ is already very ample on $C$, then from the exact sequence

$$0 \to L \to \mathcal{O}_{C'} \to \mathcal{O}_{\text{red}} \to 0$$

tensored with $h$, we obtain

$$0 \to H^0(\mathbb{P}^1, L \otimes h) \to H^0(C', h) \to H^0(\mathbb{P}^1, h).$$

Since $h$ is very ample on $C'$, we have $\dim H^0(C', h) \geq 3$, and $H^0(\mathbb{P}^1, h)$ being 2-dimensional, it follows that $H^0(\mathbb{P}^1, L \otimes h) \neq 0$, i.e. $\deg(L \otimes h) \geq 0$, proving that $\deg L \geq -1$. \qed

**Remarks 4.4.**  
(i) From what we have seen above, it is clear that if $(C, h)$ is a conic as in [4.1], then the linear system of $h$ in $C$ is 2-dimensional and imbeds $C$ as a conic in $\mathbb{P}^2$. In particular, if $C$ is a subscheme of $\mathbb{P}^n$ and $C$ is a conic with respect to the restriction of the hyperplane bundle, then $C$ is contained in a unique plane in $\mathbb{P}^n$ as a conic.

(ii) Also, if $C$ is a subscheme of the one-point union of two projective spaces, and $C$ is a conic with respect to the restriction of the natural very ample (hyperplane) bundle on this union, then $C$ is either a conic in one of the projective spaces, or is a pair of lines, one in each of these spaces passing through their point of intersection.
(iii) Let $Y$ be the thickening of a projective space $Z$ by a surjection $\varphi : \mathcal{G} \to \Omega^1$, with $\ker \varphi$ isomorphic to the dual of the universal quotient bundle $Q$ on $Z$. In this case, the hyperplane bundle on $Z$ extends uniquely to a line bundle $h$ on $Y$ which is very ample. If $C$ is a conic subscheme (with respect to $h$) of $Y$, then either (a) $C$ is a subscheme of $Z$ or (b) $C_{\text{red}}$ is a line $l$ in $Z$ and $C$ is obtained as a $\tau^{-1}$-thickening of this line in $Y$. By 3.3, the latter is obtained as a quotient of $N_{l,Z}$ which is isomorphic to $\tau^{-1}$. Consider the diagram on $l$:

\[
\begin{array}{ccccccccc}
0 & \rightarrow & Q & \rightarrow & \mathcal{G}' & \rightarrow & \tau^{-1} \otimes \text{trivial} & \rightarrow & 0 \\
| & & | & & | & & | & & \\
0 & \rightarrow & Q & \rightarrow & \mathcal{G} & \rightarrow & \Omega^1_Z & \rightarrow & 0 \\
| & & | & & | & & | & & \\
\Omega^1_l & \rightarrow & \Omega^1_l & \rightarrow & 0 & \rightarrow & 0 \\
\end{array}
\]

Now $H^0(l, \text{Hom}(Q, \tau^{-1}))$ is 1-dimensional, since $Q|l \simeq \tau^{-1} + \text{trivial}$. Hence any map $\mathcal{G}' \rightarrow \tau^{-1}$ when restricted to $Q$ must coincide (upto a scalar factor) with the natural map $Q|l \rightarrow \tau^{-1}$. If this map is zero, then the map $\mathcal{G}' \rightarrow \tau^{-1}$ factors through $(\tau^{-1} \otimes \text{trivial})$ and in this case, $C$ is actually contained in $Z$ itself. All other $\tau^{-1}$ thickenings in $Y$ are parametrised by an affine space of dim = codim of $l$ in $Z$.

(iv) If $C$ is a conic over $T$, by [9, SGA 6, VII], the morphism $\pi : C \to T$ is a complete intersection. Let $\omega$ be the relative
dualising sheaf over $T$. Then clearly $C$ is imbedded as a $T$-scheme in the projective plane bundle $S$ over $T$ associated to $E = R^1(\pi)_*\omega^2$. Moreover, if $C$ is imbedded as a $T$-scheme in a projective bundle $P$ over $T$ such that the fibres of $\pi$ are imbedded as conics, then the inclusion $C \hookrightarrow P$ factors through an imbedding $S \subset P$, linear on fibres. On $E$, there is on everywhere nontrivial quadratic form with values in a line bundle $L$ such that $C$ is the associated conic bundle over $T$.

5 Good Hecke Cycles

If $E$ is a vector bundle ($\neq 0$) on $X$ and $k \in \mathbb{Z}$, we denote by $\mu_k(E)$ the rational number $(\deg E + k)/\text{rk } E$.

Definition 5.1. A vector bundle $E$ on $X$ is said to be $(k, l)$-stable (resp. $(k, l)$-semistable) if, for every proper subbundle $F$ of $E$, we have

$$\mu_k(F) < \mu_{-l}(E/F) \text{ (resp. } \mu_k(F) \leq \mu_{-l}(E/F)\text{).}$$

Remark 5.2. (i) The condition is equivalent to $\mu_k(F) < \mu_{k-l}(E)$ or $\mu_k(F) < \mu_{-l}(E/F)$.

(ii) If $E$ is $(k, l)$-stable and $L$ any line bundle, then $E \otimes L$ is also $(k, l)$-stable.

(iii) If $E$ is $(k, l)$-stable, then $E^*$ is $(l, k)$-stable.

(iv) A vector bundle of degree 0 is stable if and only if it is $(0, 1)$-stable.

(v) A vector bundles of degree 1 is stable if and only if it is $(0, 1)$-semi-stable.

Proposition 5.3. In any family $E$ of vector bundles on $X$, parametrised by $T$, the set of $(k, l)$-stable points is open in $T$. 
Proof. Consider the Quot-scheme of $E$ over $T$. The set of non-$(k, l)$-stable points is characterised as the union of the images of the components of the Quot scheme whose Hilbert polynomials satisfy an inequality which constrain them to vary over a finite set. Now our assertion follows from the properness of the Hilbert scheme over $T$, with a fixed Hilbert polynomial. □

Proposition 5.4. (i) Except when $g = 2$, $n = 2$ and $d$ odd, there always exist $(0, 1)$-stable (and $(1, 0)$-stable) bundles of rank $n$ and degree $d$.

(ii) There exist $(1, 1)$-stable bundles of rank $n$ and degree $d$, except in the following cases.

(a) $g = 3$, and $d$ both even
(b) $g = 2$, $d \equiv 0, \pm 1(\text{mod } n)$
(c) $g = 2$, $n = 4$, $d \equiv 2(\text{mod } 4)$.

Proof. It is enough to estimate the dimension of the subvariety of $U(n, d)$, consisting of non-$(0, 1)$-stable (resp. non-$ (1, 1)$-stable) points and prove that it is a proper subvariety. Clearly any such bundle $E$ contains a subbundle $F$ satisfying the inequality

$$\frac{\deg F}{rk F} \geq \frac{\deg E - 1}{rk E}$$

(resp.)

$$\frac{\deg F + 1}{rk F} \geq \frac{\deg E}{rk E}$$

By using [5] Proposition 2.6] as in [5] Lemma 6.7] we may as well assume that $F$ and $E/F$ are stable and compute the dimension of such bundles $E$. The dimension of a component corresponding to a fixed rank $r$ and degree $\delta$ of $F$, is majorised by $\dim U(r, \delta) + \dim U(n - r, d - \delta) + \dim H^1(X, \text{Hom}(E/F, F)) - 1 = (g - 1)(n^2 - nr + r^2) + 1 + (dr - \delta n)$. In order to show this is $< \dim U(n, d) = n^2(g - 1) + 1$ we have only to verify that $(g - 1)r(n - r) > dr - \delta n$. But this is a simple consequence of the inequality $dr - \delta n \leq r$ in the first case and $\leq n$ in the second case, taking into account the exceptions mentioned in the proposition. □
**Lemma 5.5.** Let \( x \in X \) and \( 0 \to E' \to E \to \mathcal{O}_X \to 0 \) be an exact sequence of sheaves with \( E, E' \) locally free. If \( E \) is \((k, l)\)-stable then \( E' \) is \((k, l - 1)\) stable. In particular, if \( E \) is \((0, 1)\)-stable then \( E' \) is stable. Similar statements are valid when stable is replaced by semistable.

**Proof.** Let \( F \) be a subbundle on \( E' \) and \( F' \) the subbundle of \( E \) generated by the map \( F \to E \). Then \( F \to F' \) is of maximal rank and hence \( \deg F' \geq \deg F \). Now \( \mu_k(F) \leq \mu_k(F') < \mu_{k-l}(E) = \mu_{k-l+1}(E') \) as \( \deg E = \deg E' + 1 \). This proves that \( E' \) is \((k, l - 1)\) stable. \( \square \)

**Lemma 5.6.**

(i) Let \( E \) be a \((0, 1)\)-stable vector bundle of rank \( n \) and \( E' \) a stable vector bundle of rank \( n \) and determinant isomorphic to \( \det E \otimes L_x^{-1} \). If \( f : E' \to E \) is a non-zero homomorphism, we have an exact sequence

\[
0 \to E' \to E \to \mathcal{O}_X \to 0.
\]

(ii) Moreover \( \dim H^0(X, \text{Hom}(E', E)) \leq 1 \).

**Proof.** The map \( f \) is of maximal rank. For, otherwise, let

\[
\begin{array}{ccc}
E' & \longrightarrow & G' \\
\downarrow & & \downarrow \\
E & \leftarrow & G \\
\end{array}
\]

be the canonical factorisation of \( f \), where \( \text{rk} \ G' < n \) and \( G' \to G \) is of maximal rank. We then have \( \mu(G) \geq \mu(G') > \mu(E') = \mu_{-1}(E) \) which contradicts the \((0, 1)\)-stability of \( E \). Now the induced map \( \wedge f : \wedge E' \to \wedge E \) is non-zero and can vanish only at \( x \) (with multiplicity 1). Thus \( f \) is of maximal rank at all points except \( x \) and is of rank \((n - 1)\) at \( x \). This proves the first part.

If \( f \) and \( g \) are two linearly independent homomorphisms \( E' \to E \), then for \( y \neq x \), we can find a suitable (nontrivial) linear combination of \( f \) and \( g \) which is singular at \( y \), see [4] Lemma 7.1. This contradicts i) and completes the proof of Lemma 5.6. \( \square \)
Let now $W \to X \times S$ be a family of $(0, 1)$-stable vector bundles on $X$, with fixed determinant $\xi$, parametrised by $S$. Then we may construct a family $H(W)$ of vector bundles on $X$, parametrised by the associated projective bundle $\pi : P(W^*) \to X \times S$ as follows. It is easy to construct as in [5 § 4] a canonical surjection of the bundle $p_2^*\pi^*W$ on $X \times P(W^*)$ onto $p_2^*\tau \otimes O_{P(W^*)}$, where $P(W)^*$ is considered a divisor in $X \times P(W^*)$, by the inclusion $(p_1 \circ \pi, Id)$. The kernel of this homomorphism is the vector bundle $H(W)$. Let $K(W)$ be its dual.

**Remark 5.7.** This construction is the same as that in [5], except that here we have allowed $x$ also to vary on the curve. From this point of view, the families constructed in [5] may properly be denoted $H_x(V)$, $K_x(V)$, etc.

By Lemma 5.5, $K(W)$ is a family of stable vector bundles on $X$ with determinant of the form $\xi^{-1} \otimes L_x$, $x \in X$. More precisely, we have a morphism $\theta_{K(W)} : P(W^*) \to U(n, \xi^{-1}X)$ with a commutative diagram

\[
P(W^*) \xrightarrow{(\theta_{K(W)}, p_2 \circ \pi)} U(n, \xi^{-1}X) \times S \\
X \times S \xrightarrow{Id} X \times S
\]

where $\alpha : U(n, \xi^{-1}X) \to X$ is given by $L_{\alpha(E)} = (\det E) \otimes \xi^{-1}$ for $E \in U(n, \xi^{-1}X)$.

**Lemma 5.9.** The morphism $(\theta_{K(W)}, p_2 \circ \pi)$ of $P(W)^*$ in (5.8) is a closed immersion.

To prove this we will need the following

**Lemma 5.10.** Let $X$ be a scheme proper/k and $\mathcal{F}$ a coherent sheaf of $\mathcal{O}_X$-Modules. Let $S$ be a scheme and

\[
0 \to \mathcal{H} \to p_1^*\mathcal{F} \to \mathcal{G} \to 0
\]
be an exact sequence of coherent sheaves over $X \times S$ with $\mathcal{G}$ flat over $S$. Then $\mathcal{H}$ is a flat family of $\mathcal{O}_X$-Modules parametrised by $S$ and its infinitesimal deformation map at $s_0 \in S$, is the negative of the composite of the natural map $T_{s_0} \to H^0(X, \text{Hom}(\mathcal{H}_0, \mathcal{G}_0))$ (the differential of the morphism $S \to \text{Quot}$) and the boundary homomorphism $H^0(X, \text{Hom}(\mathcal{H}_0, \mathcal{G}_0)) \to \text{Ext}^1(X, \mathcal{H}_0, \mathcal{H}_0)$ associated to the sequence $0 \to \mathcal{H}_0 \to \mathcal{F} \to \mathcal{G}_0 \to 0$. Here $\mathcal{H}_0, \mathcal{G}_0$ denote the restrictions of $\mathcal{H}, \mathcal{G}$ to $X \times s_0$.

Proof. It is clearly sufficient to consider the case $S = \text{Spec } k[\epsilon]$. To give a sheaf $\mathcal{L}$ on $X \times S$ flat over $S$ which extends a given sheaf $\mathcal{L}_0$ on $X \times s_0$, is the same as giving an extension

$$0 \to \epsilon \mathcal{L}_0 \to \mathcal{L} \to \mathcal{L}_0 \to 0$$

on $X$, where $\epsilon \mathcal{L}_0$ is another copy of $\mathcal{L}_0$. This identifies the space of infinitesimal deformations of $\mathcal{L}_0$ with $\text{Ext}^1(X, \mathcal{L}_0, \mathcal{L}_0)$. In particular, $p_1^* \mathcal{F}$ is given by $\epsilon \mathcal{F} \oplus \mathcal{F}$. Now the map $p_1^* \mathcal{F} \to \mathcal{G}$ gives rise to a map $\mathcal{H}_0 \to \mathcal{F} \to \epsilon \mathcal{F} \oplus \mathcal{F} \to \mathcal{G}$. This map goes into $\epsilon \mathcal{G}_0$ and hence induces an element $t$ of $H^0(X, \text{Hom}(\mathcal{H}_0, \mathcal{G}_0))$ and thus identifies this space with the fibre of $\text{Quot}_X(k[\epsilon]) \to \text{Quot}_X(k)$ over $\mathcal{G}_0$. We have a map $\mathcal{H} \to \epsilon \mathcal{F}$ obtained by composing $\mathcal{H} \to p_1^* \mathcal{F}$ with the projection $p_1^* \mathcal{F} \to \epsilon \mathcal{F}$. This fits in a commutative diagram

$$
\begin{array}{cccccc}
0 & \longrightarrow & \epsilon \mathcal{H}_0 & \longrightarrow & \mathcal{H} & \longrightarrow & \mathcal{H}_0 & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & \epsilon \mathcal{H}_0 & \longrightarrow & \epsilon \mathcal{F} & \longrightarrow & \epsilon \mathcal{G}_0 & \longrightarrow & 0
\end{array}
$$

The last vertical map in the diagram is easily checked to be $-t$. Hence the element of $\text{Ext}^1(X, \mathcal{H}_0, \mathcal{H}_0)$ giving the extension $\mathcal{H}$ is the image of $-t$ under the connecting homomorphism

$$\text{Hom}(X, \mathcal{H}_0, \mathcal{G}_0) \to \text{Ext}^1(X, \mathcal{H}_0, \mathcal{H}_0).$$
Remark 5.11. Proposition 3.3 of [5] is a particular case of 5.10, where \( F \) and \( G \) are locally free, in which case \( \text{Ext}^1(X, \mathcal{H}_0, \mathcal{H}_0) \) is the same as \( H^1(X, \text{End} \mathcal{H}_0) \).

Proof of Lemma 5.9. In view of the diagram 5.8, we may assume that \( T \) is a point. Thus we have a bundle \( W \) on \( X \) and the exact sequence

\[
0 \to H(W) \to p_1^* W \to p_2^* \tau \otimes \mathcal{O}_{P(W^*)} \to 0
\]

on \( X \times P(W^*) \). Now it is easy to see that \( P(W^*) \) is a component of Quot \( E \) and hence its tangent bundle can be identified as in Lemma 5.10, with

\[
(p_2)_*(\text{Hom}(H(W), \tau \otimes \mathcal{O}_{P(W^*)})) = \text{Hom}(H(W)|P(W^*), \tau).
\]

Moreover, by Lemma 5.10, the infinitesimal deformation map for the family \( H(W) \) of bundles on \( X \) is given, up to sign, by the connecting homomorphism

\[
\text{Hom}(H(W)|P(W^*), \tau) \to R^1(p_2)_* \text{End} H(W).
\]

But this fits in the exact sequence

\[
0 \to (p_2)_*(\text{End} H(W)) \to (p_2)_*(\text{Hom}(H(W), p_1^* W)) \to \\
\text{Hom}(H(W)|P(W^*), \tau) \to R^1(p_2)_* \text{End} H(W).
\]

Now since \( H(W) \) is a family of stable bundles,

\[
(p_2)_*(\text{End}(H(W))) \simeq \mathcal{O}_{P(W^*)}
\]

and by Lemma 5.6 (ii), the same is true of

\[
(p_2)_*(\text{Hom}(H(W), p_2^*(W))).
\]

This proves that the differential of the map \( \theta_{K(E)} : P(W^*) \to U(n, \xi^{-1} X) \) is injective. On the other hand, \( \theta_{K(E)} \) is itself injective by Lemma 5.6 (ii), thus proving Lemma 5.9.
Now, for each family of $(0, 1)$-stable bundles we have a morphism of the parameter space into $U(n, \xi^{-1}X)$, by Lemma 5.9. Since these morphisms are clearly functorial we get a morphism $\Phi$ on the open subscheme of $U(n, \xi)$ consisting of $(0, 1)$-stable points into the Hilbert scheme $\text{Hilb}(U(n, \xi^{-1}X))$.

**Definition 5.12.** The cycles in $U(n, \xi^{-1}X)$ corresponding to $(0, 1)$-stable points of $U(n, \xi)$ will be called good Hecke cycles. Any subscheme in the same irreducible component of the Hilbert scheme will be called a Hecke cycle.

**Theorem 5.13.** Let $\xi$ be a line bundle on $X$. The open subscheme of $U(n, \xi)$ consisting of $(0, 1)$-stable points is isomorphic (by means of the map associating to a bundle $W$ the corresponding good Hecke cycle $\Phi(W)$) to an open subscheme of the Hilbert scheme of $U(n, \xi^{-1}X)$.

**Proof.** To prove the injectivity, we will check the stronger assertion that for $W, W' \in U(n, \xi)$, both $(0, 1)$-stable, $\vartheta_{K_x(W)}(P(W^*_x)) = \vartheta_{K_x(W')}(P(W'^*_x))$ if and only if $W$ and $W'$ are isomorphic. Indeed, by [6, Lemma 2.5], such an assumption would yield an isomorphism $\varphi : P(W^*_x) \to P(W'^*_x)$ such that $\varphi^*K_x(W') \cong K_x(W) \otimes p^*_2L$ on $X \times P(W^*_x)$, for some line bundle $L$ on $P(W^*_x)$. Now by [5, Remark 4.7], we see, on restricting this isomorphism to $P(W^*_x) \times (y)$, $y \neq x$, that $L$ is trivial. But then, by [5, Lemma 4.3] we have $(p_1)_*\varphi^*K_x(W')^* \cong (p_1)_*K_x(W')^* \cong L^{-1}_x \otimes W'$ on the one hand, and $(p_1)_*K_x(W')^* \cong L^{-1}_x \otimes W$ on the other. This proves that $W \cong W'$.

Next we proceed to show that, if $W \in U(n, \xi)$ is $(0, 1)$-stable, the infinitesimal deformation map at $W$ of the family of good Hecke cycles from $T_W \simeq H^1(X, \text{Ad } W)$ to $H^0(P(W^*), N)$ is an isomorphism, where $N$ is the normal bundle of $P(W^*)$ in $U(n, \xi^{-1}X)$. This would prove that the Hilbert scheme is smooth at $\Phi(W)$ and that $\Phi$ is an isomorphism onto to an open subset, as claimed. To complete the proof of the theorem we need two lemmas.

**Lemma 5.14.** Let $\pi_1 : P_1 \to U(n, \xi) \times X$ be the dual of the projective Poincaré bundle on $U(n, \xi) \times X$. Let $\pi_2 : P_2 \to U(n, \xi^{-1}X)$ be
the restriction of the dual projective Poincaré bundle on \(U(n, \xi^{-1}X)\times X\) to the divisor \(U(n, \xi^{-1}X)\). Let \(\Omega_1 \subset P_1\) and \(\Omega_2 \subset P_2\) be the open subsets of points at which the families \(K\) are stable. We then have an isomorphism \(\widetilde{\theta} : \Omega_1 \rightarrow \Omega_2\) such that \(\pi_2 \circ \widetilde{\theta} = \theta\).

**Proof.** A point \(p\) of \(\Omega_1\) is described by a \((0, 1)\)-stable vector bundle in \(U(n, \xi)\), a point \(x \in X\) and an element of \(P(E^*)_x\). Now this can be looked upon as a map \(E \rightarrow \mathcal{O}_x\) with kernel \(F\), where \(F^*\) belongs to \(U(n, \xi^{-1}X)\). By looking at the map \(F_x \rightarrow E_x\) of the fibres at \(x\), we can define a map \(\Omega_1 \rightarrow P_2\) by associating the \(\ker F_x\) to \(p\). It is easy to see that this lift of \(\theta\) maps \(\Omega_1\) isomorphically onto \(\Omega_2\). In fact this map is induced by the section \(\sigma\) [5, p. 402].

**Lemma 5.15.** Let \(W \in U(n, \xi)\) be \((0, 1)\)-stable. Then the normal bundle \(N = N_{P(W^*), U(n, \xi^{-1}X)}\) of \(P(W^*)\) in \(U(n, \xi^{-1}X)\) fits into an exact sequence

\[
0 \rightarrow p_X^*T_X \otimes T_\pi^* \rightarrow P(W^*) \times T_W \rightarrow N \rightarrow 0.
\]

**Proof.** Since \(W\) is \((0, 1)\)-stable, \(P(W^*) = (p_2 \circ \pi_1)^{-1}W\) is contained in \(\Omega_1\) and \(N_{P(W^*), \Omega_1} \cong P(W^*) \times T_W\). Moreover \(N_{P(W^*), \Omega_1} \cong N_{\widetilde{\theta}(P(W^*)), \Omega_2}\). Since \(\pi_2 \circ \theta = \theta\), and \(\theta|P(W^*)\) is an imbedding (Lemma 5.9), we see that \(\widetilde{\theta}(P(W^*))\) is transversal to the fibres of \(\pi_2\). Hence we have an exact sequence (on \(P(W^*)\))

\[
0 \rightarrow \widetilde{\theta}^*T_{\pi_2} \rightarrow N_{\widetilde{\theta}(P(W^*)), \Omega_2} \rightarrow N_{(\theta(P(W^*))), U(n, \xi^{-1}X)} \rightarrow 0.
\]

But by Proposition 4.12 in [5], we have \(\widetilde{\theta}^*T_{\pi_2} \cong (p_2 \circ \pi_1)^*T_X \otimes T_\pi^*\). This proves the Lemma.

**Completion of the Proof of Theorem 5.13.** Taking the direct image of the exact sequence in Lemma 5.15 and noting that, \(H^0(X, T_X) = 0\), we see that the natural map \(T_W \rightarrow H^0(P(W^*), N)\) is an isomorphism. But this is clearly the differential of \(\Phi\) at \(W\).
Taking determinants in the exact sequence 5.15, we obtain

**Corollary 5.16.** Let $P(W^*)$ be a good Hecke cycle in $U(n, \xi^{-1}X)$. Then the line bundle $K_{\text{det}}$ on $U_X$ restricts to $P(W^*)$ as $\pi^* K_X^{-(n-1)} \otimes K^2_{\pi}$. 

**Remarks 5.17.**

(i) Although the Hilbert scheme in Theorem 5.11 is smooth, $H^1(P(W^*), N) \neq 0$ unlike the case discussed below.

(ii) Let us now fix $x \in X$. The open subset $\Omega_0$ of points in the projective dual Poincaré bundle over $U(n, \xi) \times (x)$, corresponding to the family $K_x$, is isomorphic to a similar open subset of the projective Poincaré bundle over $U(n, \eta) \times (x)$ where $\xi \otimes \eta = L_x$. Thus we have two maps

\[ \xymatrix{ \Omega_0 \ar[d]_{\pi_1} \ar[r]_{\pi_2} & U(n, \xi) \ar[d] \ar[r] & U(n, \eta) \ar[d] } \]

which are projective fibrations over the open subsets of $(0, 1)$-stable points of $U(n, \xi)$, $U(n, \eta)$ respectively. Now the content of [5, Proposition 4.12] is that $T^*_{\pi_1} \simeq T_{\pi_2}$. (See also [8a, Ch 5, § 1]). If $W$ is a $(0, 1)$-stable point of $U(n, \xi)$, then $\pi_1^{-1}(W)$ is imbedded by $\pi_2$, thus giving a family of cycles in $U(n, \eta)$ parametrised by the $(0, 1)$-stable points of $U(n, \xi^{-1}X)$. For the normal bundle $N$ of the cycle $\Phi(W)$ corresponding to $W$ we have the exact sequence

\[ 0 \to \Omega^1_{P(W^*)} \to H^1(X \text{ Ad } W)_{P(W^*)} \to N \to 0. \]

This shows that $H^1(\Phi(W), N) = 0$ for $i \geq 1$ and

\[ \dim H^0(\Phi(W), N) = \dim H^1(X, \text{ Ad } W) + 1. \]

As in Theorem 5.13 we see that the open subset of $(0, 1)$-stable points of $U(n, \xi^{-1}X)$ can be identified with an open subset of a component of the Hilbert scheme of $U(n, \xi)$. 

---

*Geometry of Hecke Cycles - I* 367
(iii) If $W$ is a $(1, 1)$-stable bundle in $U(n, \xi)$, the corresponding cycle $\Phi(W)$ in $U(n, \xi^{-1}X)$ which is isomorphic to $P(W^*)$, is contained entirely in the set of $(0, 1)$-stable points (Lemma 5.5 and Remark 5.2 (iii)). By the reverse construction in (ii), $P(W^*)$ is contained in the Hilbert scheme of $U(n, \xi)$ consisting of good Hecke cycles (this time, isomorphic to a projective space) passing through $W$. Thus $P(W^*)$ can be identified with this subscheme of the Hilbert scheme. From this one may conclude that any continuous group of automorphism of $U(n, \xi)$ lifts to the projective Poincaré bundle over some open subset of $U(n, \xi)$ consisting of $(1, 1)$ stable points. Thus, if $(1, 1)$-stable points exist, then the automorphism group of $U(n, \xi)$ is finite. This was our original approach to the Theorems 1, 2 of [5].

6 Triangular bundles

We will deal with the case of rank 2 bundles in the rest of the paper. We will denote $U(2, \xi)$ (resp. $U(2, L_x)$) by $U_\xi$ (resp. $U_x$). When $\xi$ is trivial we write $U_\xi = U_0$.

We wish to study the limits of good Hecke cycles, i.e., points in the component of the Hilbert scheme, containing good Hecke cycles. It will turn out (§ 7) that these cycles consist of bundles which are extensions of line bundles of a particular kind. These bundles have been studied in [6] and [8] and the computations made in this article result from a closer analysis of the situation.

Let $R$ be a Poincaré bundle on $X \times J$, where $J$ is the Jacobian of $X$, Consider on $X \times X \times J$ the bundle $p_{13}^* R^2 \otimes p_{12}^* L^{-1}_\Delta$, where $\Delta$ is the diagonal in $X \times X$. Then the first direct image $R_1^1 (p_{23})_*(p_{13}^* R^2 \otimes p_{12}^* L^{-1}_\Delta)$ on $X \times J$ is clearly a vector bundle $D$. For each $j \in J$, the restriction of $D$ to $X \times j$ gives rise to a bundle $D_j$ on $X$.

**Lemma 6.1.** If $j^2 \neq 1$, then the bundle $D_j$ fits in an exact sequence

$$0 \to j^2 \to D_j \to H^1(X, j^2) \to 0$$
given by the identity element of $H^1(X \text{Hom}(H^1(X, j^2), j^2))$. If $j^2 = 1$, then $D_j$ is isomorphic, up to tensorisation by a line bundle, to $H^1(X, \mathcal{O})_X$. In particular, $D_j$ is a semistable vector bundle of degree 0 and any nonzero subbundle of $D_j$ of degree 0 is the inverse image of a trivial subbundle of $H^1(X, j^2)_X$.

**Proof.** By the base change theorem, the bundle $D_j$ is isomorphic to $R^1(p_2)_*(p_1^*j^2 \otimes L^{-1}_\Delta)$, where $p_1$, $p_2$ are the projections $X \times X \to X$. Hence it is dual to $(p_2)_*(p_1^*(K \otimes j^{-2}) \otimes L_\Delta)$. Consider on $X \times X$ the exact sequence

$$0 \to p_1^*(K \otimes j^{-2}) \to p_1^*(K \otimes j^{-2}) \otimes L_\Delta \to \tilde{j}^{-2} \to 0,$$  

where the sheaf $\tilde{L}$ denotes the extension of a line bundle $L$ on $\Delta$ to $X \times X$ and we have used the fact that $L_\Delta|_\Delta \cong K^{-1}_X$. We will show that by applying $(p_2)_*$ to this sequence and dualising, we get the canonical extension in 6.1. Now the pullback by $p_2^*j^{-2} \to \tilde{j}^{-2}$ of this sequence yields an extension of $p_2^*j^{-2}$ by $p_1^*(K \otimes j^{-2})$. The corresponding element in $H^1(X \times X, p_2^*j^{-2} \otimes p_1^*(K \otimes j^{-2})) = H^0(X, K \otimes j^{-2}) \otimes H^1(X, j^2)$ (since $j^2 \neq 1$) is the canonical element given by the duality theorem. Thus it is clear that this pullback extension is also the push-out by the evaluation map $H^0(K \otimes j^{-2})_{X \times X} \to p_1^*(K \otimes j^{-2})$ of the extension

$$0 \to H^0(X, K \otimes j^{-2})_{X \times X} \to \ldots \to p_2^*j^{-2} \to 0$$

given by the canonical element of $H^1(X \times X, p_2^*j^2 \otimes H^0(X, K \ot \otimes j^{-2}))$. Hence the exact sequence obtained by taking direct image by $p_2$, namely,

$$0 \to H^0(X, K \otimes j^{-2}) \to \ldots \to j^{-2} \to 0$$

is again given by the canonical element. But this is also obtained by taking the direct image of the sequence (6.2), thus proving the first part of Lemma 6.1. If $j^2 = 1$, then $D_j = R^1(p_2)_*(L^{-1}_\Delta) \cong H^1(X, \mathcal{O})_X$ as is seen from the exact sequence

$$0 \to L^{-1}_\Delta \to \mathcal{O} \to \tilde{\mathcal{O}} \to 0.$$
If $F$ is a subbundle of degree 0, then $F \cap j^2 = 0$ or $F \supset j^2$. In either case, the image of $F$ in $H^1(X, j^2)_X$ is a subbundle of degree 0 and hence trivial. If $F \cap j^2 = 0$, this would imply that the extension $0 \to j^2 \to D_j \to H^1(X, j^2)_X \to 0$ splits over a trivial subbundle of $H^1(X, j^2)_X$ which is seen to be not possible, in view of our description of this extension.

**Lemma 6.3.** Let $C = \{(x, j) \in X \times J : j^{-2} \otimes L_x \in X\}$. Then

(i) the bundle $P(D)$ is trivial on $C$.

(ii) $X \times j \subset C$ if and only if $j$ is an element of order 2.

**Proof.** (i) On $X \times C$, the bundle $(p_{13})^* R^2 \otimes (p_{12})^* L_{\Delta}^{-1}$ is isomorphic to $p_C^* \zeta \otimes (1 \times \alpha)^* L_{\Delta}^{-1}$ where $\zeta$ is some line bundle on $C$ and $\alpha : C \to X$ is the map defined by $L_{\alpha(x, j)} = j^{-2} \otimes L_x$. Hence $D|C$ is isomorphic (by base change theorem) to $\zeta \otimes \alpha^*(R^1(p_2)_* L_{\Delta}^{-1})$. But clearly $R^1(p_2)_* L_{\Delta}^{-1} \cong H^1(X, \mathcal{O})_X$.

(ii) If $j$ is an element of order 2, clearly $X \times j \subset C$. On the other hand, if $X \times j \subset C$, then $D_j = D|_{X \times j} \cong (\zeta|X \times j) \otimes$ trivial bundle, and hence by Lemma 6.1, this is possible only if $j$ is an element of order 2.

We now have a family $E$ of (triangular) vector bundles on $X \times P(D)$ given by [6, Lemma 2,4]:

$$0 \to (1 \times \pi)^* p_{13}^* R \otimes p_2^* \tau \to E \to (1 \times \pi)^* p_{13}^* R^{-1} \otimes (1 \times \pi)^* p_{12}^* L_{\Delta} \to 0$$

(6.4)

where $\pi : P(D) \to X \times J$ is the projective fibration associated to $D$.

The bundle $E$ on $X \times P(D)$ is a family of stable vector bundles [3, Lemma 10.1 (i)] on $X$ of rank 2 and determinants of the form $L_x, x \in X$. Thus there is an induced classifying morphism $\theta_E :$
\[ P(D) \to U_X \] fitting in an obvious commutative diagram

\[
\begin{array}{ccc}
P(D) & \xrightarrow{\theta_E} & U_X \\
p_1 \circ \pi & & det \\
X & \xrightarrow{\text{Id}} & X
\end{array}
\]

(6.5)

We now wish to study the morphism \( \theta_E \) and, in particular, its differential. Clearly \( E \) is a family of bundles with the triangular group as structure group. As such, there is an infinitesimal deformation map \( T_{P(D)} \to R^1(p_2)_*(\Delta(E)) \) where \( \Delta(E) \) is the bundle of endomorphisms of \( E \) preserving the exact sequence \( (6.4) \). This is because the associated bundle with the Lie algebra of the triangular group as fibre is \( \Delta(E) \). (Remark 2, 13, i).

**Lemma 6.6.** The above infinitesimal deformation map induces an isomorphism of \( T_{p_1 \circ \pi} \) with the kernel of \( R^1(p_2)_*(\Delta(E)) \to R^1(p_2)_*(\mathcal{O}) \) given by the trace map \( \Delta(E) \to \mathcal{O} \) and hence with \( R^1(p_2)_*(S \Delta(E)) \), where \( S \Delta(E) \) is the subbundle of \( \Delta(E) \) consisting of endomorphisms of trace 0.

**Proof.** In view of the diagram (6.5) it is clear that \( T_{p_1 \circ \pi} \) is mapped into the kernel. From the diagram of exact rows (on \( P(D) \)),

\[
\begin{array}{c}
0 \\
0 \\
R^1(p_2)_*(E \otimes (1 \times \pi)^*(p_{13}^* R \otimes p_{12}^* L_{-1}^-)) \\
R^1(p_2)_*(\Delta(E)) \\
H^1(X, \mathcal{O}_{P(D)}) \\
0
\end{array}
\]

we see that it is enough to show that the infinitesimal deformation map maps \( T_\pi \) isomorphically on \( R^1(p_2)_*(E \otimes R \otimes L_{-1}^-) \), since it is obvious that the last vertical map is an isomorphism. Indeed, we have \( \Box \)

**Lemma 6.7.** Let \( V, W \) be two simple vector bundles on \( X \). Let \( P = PH^1(X, \text{Hom}(W, V)) \), and

\[
0 \to p_1^* V \otimes p_2^* \tau \to E \to p_1^* W \to 0
\]
be the universal exact sequence on $X \times P$ (see [6, Lemma 2.3]). Then the infinitesimal deformation map of the family $E$ of bundles with the evident parabolic group as structure group, maps $T_P$ isomorphically onto the kernel of $R^1(p_2)_*(E \otimes p_1^*W^*) \to R^1(p_2)_*(\operatorname{End} W)$.

**Proof.** From the definition of the universal extension, it follows that the map $\mathcal{O}_P = (p_2)_*(W \otimes W^*) \to R^1(p_2)_*(V \otimes \tau \otimes W^*) = H^1(X, V \otimes W^*) \otimes \tau$ is the natural inclusion. Hence its cokernel is isomorphic to the tangent bundle $T_P$ of $P$. From the cohomology exact sequence obtained from the given sequence tensored with $W^*$, we obtain an isomorphism of $T_P$ with the kernel of $R^1(p_2)_*(E \otimes p_1^*W^*) \to R^1(p_2)_*(\operatorname{End} W)$. We have to check that this identification is the infinitesimal deformation map. This verification can be done by choosing splittings for the given sequence over $U_i \times P$ where $(U_i)$ is an open covering of $X$ and expressing the infinitesimal deformation map in terms of Čech cocycles with respect to this covering. □

**Proposition 6.8.** Recall that $C = \{(x, j) \in X \times J : j^{-2} \otimes L_x \in X\}$. The differential $d\theta_E$ is injective outside $\pi^{-1}(C)$ and $\ker d\theta_E$ is a line bundle on $\pi^{-1}(C)$.

**Proof.** Consider the exact sequence obtained from [6.4]

$$0 \to S \Delta(E) \to \operatorname{Ad} E \to (1 \times \pi)^*(p_{13}^*R^{-2} \otimes p_{12}^*L_{\Delta}) \otimes p_2^*\tau^{-1} \to 0.$$  

(6.9)

Take the direct image on $P(D)$. The (zeroth) direct image of the bundle on the right is zero since it is clearly torsion free and zero outside $\pi^{-1}(C)$. Thus we get a short exact sequence (using Lemma 6.6)

$$0 \to T_{p_1 \circ \pi} \to R^1(p_2)_*(\operatorname{Ad} E) \to R^1(p_2)_*(R^{-2} \otimes L_{\Delta}) \otimes \tau^{-1} \to 0.$$  

From [6 Lemma 2.6], we have $R^1(p_2)_*(\operatorname{Ad} E) = \theta^*_E T_{\det}$ and it is easy to see that the first map is $d\theta_E$. Moreover, outside $\pi^{-1}(C)$, the last term in this sequence is clearly locally free of rank $(g - 2)$ while its restriction to $\pi^{-1}(C)$ is also locally free of rank $(g - 1)$. This proves the proposition. □
Identifying $\pi^{-1}(C)$ with $C \times P$ where $P = PH^1(X, \mathcal{O})$, the restriction of $E$ to $X \times C \times P$ can be described as follows.

**Lemma 6.10.**

(i) There is a natural isomorphism $H^1(X \times C \times P, p_3^*\tau \otimes p_{12}^*(1 \times \alpha)^*L_\Delta^{-1})$ with $H^1(X, \mathcal{O}) \otimes H^1(X, \mathcal{O})^*$.

(ii) The family $E \otimes p_{13}^*R^{-1}$ restricts to $X \times C \times P$ as an extension

$$0 \rightarrow p_3^*\tau \rightarrow E \otimes p_{13}^*R^{-1} \rightarrow p_{12}^*(1 \times \alpha)^*L_\Delta \rightarrow 0$$

given by the canonical element in $H^1(X, \mathcal{O}) \otimes H^1(X, \mathcal{O})^*$, using the isomorphism in (i).

**Proof.** Note that $H^1(X \times C, (1 \times \alpha)^*L_\Delta^{-1}) \simeq H^0(C, R^1(p_2)_*(1 \times \alpha)^*L_\Delta^{-1}) \simeq H^0(C, \alpha^*R^1(p_2)_*\mathcal{O}_{X \times X}) \simeq H^1(X, \mathcal{O})_C$. This proves (i). That the canonical element gives the required extension follows from the definition of $E$ and the base change theorem. □

**Proposition 6.11.** Let $0 \rightarrow p_2^*\tau \rightarrow F' \rightarrow \mathcal{O} \rightarrow 0$ be the universal extension of $\mathcal{O}$ by $\tau$ on $X \times PH^1(X, \mathcal{O})$. Then the restriction of $T_{p_1 \circ \pi}$ to $\pi^{-1}(C) = C \times P$ is isomorphic to the quotient of $F' \otimes H^1(X, \mathcal{O})$ by the trivial subbundle contained in $p_2^*\tau \otimes H^1(X, \mathcal{O})$.

**Proof.** We will apply Lemma 6.6 and use the description of $E|X \times C \times P$ given in Lemma 6.10. Thus we have the extension

$$0 \rightarrow p_3^*\tau \otimes p_{12}^*(1 \times \alpha)^*L_\Delta^{-1} \rightarrow S\Delta(E) \rightarrow \mathcal{O} \rightarrow 0.$$
This may be embedded in the commutative diagram

$$
\begin{align*}
0 & \quad 0 \\
0 \rightarrow p_3^* \tau \otimes (1 \times \alpha)^* L_{\Delta}^{-1} & \rightarrow S \Delta(E) & \rightarrow \mathcal{O} & \rightarrow 0 \\
0 \rightarrow p_3^* \tau & \rightarrow F'' & \rightarrow \mathcal{O} & \rightarrow 0 \\
p_3^* \tau \otimes \mathcal{O}_{\text{Graph } \alpha} & = p_3^* \tau \otimes \mathcal{O}_{\text{Graph } \alpha} & & 0 \rightarrow 0
\end{align*}
$$

(6.12)

where the middle line is obtained from the top line as the push-out by means of the map $p_3^* \tau \otimes (1 \times \alpha)^* L_{\Delta}^{-1} \rightarrow p_3^* \tau$. By Lemma 6.6, $T_{p_1 \circ \pi}|C \times P$ is isomorphic to the first direct image on $C \times P$ of $S \Delta(E)$. The middle vertical line of the above diagram yields an isomorphism of this with the first direct image of $F''$. For, $R^1(p_{23})_* (p_3^* \tau \otimes \mathcal{O}_{\text{Graph } \alpha})$ is clearly 0. Since $(p_{23})_* (p_3^* \tau) \rightarrow (p_{23})_* (\tau \otimes \mathcal{O}_{\text{Graph } \alpha})$ is clearly an isomorphism, it follows that $(p_{23})_* F'' \rightarrow (p_{23})_* (p_3^* \tau \otimes \mathcal{O}_{\text{Graph } \alpha})$ is surjective, proving our assertion above.

It remains to compute $R^1(p_{23})_* (F'')$. From the description of the extension in Lemma 6.10 and hence that in the top horizontal line of the diagram 6.12, it can be checked that the element in $H^1(X \times C \times P, p_3^* \tau) = H^1(X, \mathcal{O}) \otimes H^1(X, \mathcal{O})^* \oplus H^1(C, \mathcal{O}) \otimes H^1(X, \mathcal{O})^*$ given by the extension $F''$ is the element $(Id, -\alpha^*(Id))$. Indeed, this follows on remarking that the map $H^1(X, \mathcal{O}) \cong H^1(X \times X, L_{\Delta}^{-1} \Delta) \rightarrow H^1(X \times X, \mathcal{O}) \rightarrow H^1(X, \mathcal{O}) \oplus H^1(X, \mathcal{O})$ is given by $(Id, -Id)$. Now our assertion follows from □

**Lemma 6.13.** Consider on $X \times X \times P$, the exact sequence

$$
0 \rightarrow p_3^* \tau \rightarrow F_0 \rightarrow \mathcal{O} \rightarrow 0
$$

given by the element $(Id, -Id)$ in $H^1(X \times X, \mathcal{O}) \otimes H^0(P, \tau) \cong V \otimes V^* \oplus V \otimes V^*$, with $V = H^1(X, \mathcal{O})$. The direct image on $X \times P$ by
p_{23} of this sequence fits in a commutative diagram

\[
\begin{array}{cccccc}
0 & \rightarrow & p_2^* T_P & \rightarrow & R^1(p_{23})_* F_0 & \rightarrow & H^1(X, \mathcal{O}_{X \times P}) & \rightarrow & 0 \\
\uparrow & & \uparrow & & \uparrow & & \uparrow & & \uparrow \\
0 & \rightarrow & p_2^* \tau \otimes H^1(X, \mathcal{O}) & \rightarrow & F' \otimes H^1(X, \mathcal{O}) & \rightarrow & H^1(X, \mathcal{O}_{X \times P}) & \rightarrow & 0 \\
\end{array}
\]

where \( 0 \rightarrow p_2^* \tau \rightarrow F' \rightarrow \mathcal{O} \rightarrow 0 \) is the universal extension on \( X \times P \) and the first vertical map is induced by the natural map \( \tau \otimes H^1(X, \mathcal{O}) \rightarrow T_P \) on \( P \).

**Proof.** In the following Lemma, take \( L = K_X, L' = \mathcal{O}, T = X \times P \), and apply duality to prove the Lemma. \( \square \)

**Lemma 6.14.** Let

\[
0 \rightarrow p_1^* L \rightarrow M \rightarrow p_1^* L \otimes p_2^* L' \rightarrow 0
\]

be an exact sequence of vector bundles on the variety \( X \times T \). Assume that \( \dim H^0(X \times t, M) \) is independent of \( t \). Then the extension

\[
0 \rightarrow H^0(X, L)_T \rightarrow (p_T)_* M \rightarrow \ker \delta \rightarrow 0,
\]

where \( \delta \) is the connecting homomorphism

\[
H^0(X, L) \otimes L' \rightarrow H^1(X, L),
\]

is given by the image under the natural map

\[
H^1(T, L'^{-1}) \rightarrow H^1(T, (\ker \delta)^* \otimes H^0(X, L))
\]

of the Künneth component in \( H^1(T, L'^{-1}) \) of the element of \( H^1(X \times T, \text{Hom}(L, L) \otimes L'^{-1}) \) determined by the extension \( M \).

**Proof.** Let \( x_1, \ldots, x_N \) be points of \( X \) such that the evaluation map \( H^0(X, L) \rightarrow \bigoplus L_{x_i} \) is an isomorphism. This fits in a commutative diagram

\[
\begin{array}{cccccc}
0 & \rightarrow & H^0(X, L)_T & \rightarrow & (p_T)_* M & \rightarrow & \ker \delta & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \rightarrow & \sum L_{x_i} & \rightarrow & \sum M_{x_i \times T} & \rightarrow & L' \otimes \sum L_{x_i} & \rightarrow & 0
\end{array}
\]
The latter sequence is clearly defined by the required element in \( H^1(T, L^{-1}) \).

**Proposition 6.15.** The differential \( d\theta_E \) on \( \pi^{-1}C = C \times P \) fits in an exact sequence

\[
0 \to \tau^{-1} \to T_{p_1 \circ \pi}|\pi^{-1}C \xrightarrow{d\theta_E} \theta_E^*T_{\det} \to \tau^{-1} \otimes \pi^*\alpha^*F \to 0
\]

where \( F \) is the vector bundle on \( X \) defined by the exact sequence

\[
0 \to T_X \to H^1(X, \mathcal{O}) \to F \to 0
\]

corresponding to the canonical linear system and \( \alpha : C \to X \) is the map defined by \( j^{-2} \otimes L_x = L_{\alpha(j, x)} \).

**Proof.** Note that if \( \Delta \) denotes the diagonal divisor in \( X \times X \), then \( (p_2)_*(L_\Delta) \approx \mathcal{O}_X \) and \( R^1(p_2)_*(L_\Delta) \approx F \). In fact, the first of these isomorphisms is obvious and the second follows from the exact sequence (on \( X \times X \))

\[
0 \to \mathcal{O}_{X \times X} \to L_\Delta \to \tilde{T}_X \to 0
\]

where \( \tilde{T}_X \) is the sheaf on \( X \times X \) supported on \( \Delta \) and inducing \( T_X \) on it. Restricting \( \ref{6.9} \) to \( X \times C \times P \), we get the sequence

\[
0 \to S\Delta(E) \to \text{Ad} E \to p_3^*\tau^{-1} \otimes p_{12}^*(1 \times \alpha)^*L_\Delta \to 0.
\]

The direct image of this sequence, using base change for \( \alpha \), yields the lemma, in view of Lemma 6.6.

We will now compute the Hessian of the map \( \theta_E \) restricted to \( \pi^{-1}C = C \times P \). By Proposition 6.8, \( \pi^{-1}C \) is the critical set for \( \theta_E \). Moreover, \( \ker d\theta_E \) on \( C \times P \) is isomorphic to \( \tau^{-1} \) by Proposition 6.15. The Hessian is thus a map \( \tau^{-1} \otimes N_{C \times P, P(D)} \to \text{coker } d\theta_E|C \times P \). (See Remark 3.6). Now \( N_{C \times P, P(D)} \approx \pi^*N_{C, X \times J} \approx \pi^*\alpha^*N_{X, J}^1 \approx \pi^*\alpha^*F \) where \( F \) is the bundle defined in Proposition 6.15. On the other hand, by Proposition 6.15, \( \text{coker } d\theta_E|C \times P \) is isomorphic to \( \tau^{-1} \otimes \pi^*\alpha^*F \). With these identifications we have
Proposition 6.16. The Hessian on $\pi^{-1}C = C \times P$ of the map $\theta_E$ considered as a map $\tau^{-1} \otimes \pi^* \alpha^* F \to \tau^{-1} \otimes \pi^* \alpha^* F$ is the identity map.

Proof. By Lemma 6.6, the computation of the required Hessian may be made using Remark 2.13, i). From the description of the family $E$ over $X \times \pi^{-1}C$ given in Lemma 6.10, we see that the Hessian of $\theta_E$ is simply the map

$$(p_{23})_* (\tau^{-1} \otimes \alpha^* L_\Delta) \otimes R^1(p_{23})_* (\alpha^* L_\Delta^{-1} \otimes E \otimes R^{-1}) \to R^1(p_{23})_* (\tau^{-1} \otimes \alpha^* L_\Delta)$$

given by the cup product for the natural map

$$(\tau^{-1} \otimes \alpha^* L_\Delta) \otimes (\alpha^* L_\Delta^{-1} \otimes E \otimes R^{-1}) \to \tau^{-1} \otimes E \otimes R^{-1} \to \tau^{-1} \otimes \alpha^* L_\Delta.$$ 

From this it is clear that this map is the identity on $\tau^{-1}$ tensored with the induced map

$$(p_{23})_* (\alpha^* L_\Delta) \otimes R^1(p_{23})_* (\emptyset) \to R^1(p_{23})_* (\alpha^* L_\Delta).$$

Now since $(p_{23})_* (\alpha^* L_\Delta)$ is canonically trivial, this is simply the inverse image by $\alpha \circ p_1$ of the map $H^1(X, \emptyset)_X \to R^1(p_2)_*(L_\Delta)$. This is clearly the natural map $H^1(X, \emptyset)_X \to F$, proving our assertion. \qed

Remark 6.17. From Proposition 6.16 we see that $\pi^{-1}C$ is a ‘non-degenerate’ critical manifold for $\theta_E$.

Proposition 6.18. For every $j \in J$, the map $\theta_E : \pi^{-1}(X \times j) \to U_X$ is an imbedding.

Proof. We first remark that in view of 6.5, it is enough to prove that $\theta_E : \pi^{-1}(x, j) \to U_X$ is an imbedding, for every $x \in X$ and $j \in J$. Secondly, from [3, Lemma 10.1], it follows that this map is injective. Moreover, if $(x, j) \in C$, then by Proposition 6.8 $\theta_E : \pi^{-1}(x, j) \to U_X$ is an imbedding. Finally, let $(x, j) \in C$. In order to show that $d\theta_E|T\pi$ is injective, it is enough to prove that the composite of the inclusion $\tau^1 \to T_{p_1 \circ \pi}|_{C \times P}$ with the differential
$d\pi : T_{p_1 \circ \pi} \to \pi^* T_{p_1} = H^1(X, \mathcal{O})_{CP}$ is injective. Consider the commutative diagram (on $\pi^{-1}C$)

\[
\begin{array}{ccc}
0 & \xrightarrow{S \Delta(E)} & \Delta(E) \\
& \downarrow & \downarrow \\
0 & \xrightarrow{\mathcal{O}} & E \otimes (1 \times \pi)^* p_{13}^* R^{-2} \otimes p_{12}^* L_\Delta \otimes p_2^* t^{-1} \xrightarrow{\pi} 0 \\
\end{array}
\]

From this we conclude that this composite is given by the boundary homomorphism of the lower sequence. Now our assertion follows from the definition of the extension $E$. $\square$

The nonsingular subvarieties $\theta_E(\pi^{-1}(X \times j)) \subset U_X$ will also be denoted $P(D_j)$.

**Proposition 6.19.** If $j_1 \neq j_2$ or $j_2^{-1}$, then $P(D_{j_1})$ intersects $P(D_{j_2})$ in only finitely many points. If $j_2 \neq 1$, then $P(D_j)$ and $P(D_{j^{-1}})$ intersect transversally along the sections given by the exact sequence in Lemma 6.1.

**Proof.** Let $j_1 \neq j_2$, $j_2^{-1}$ and $W \in P(D_{j_1}) \cap P(D_{j_2})$. Then $W$ is given by an extension

\[
0 \to j_1 \to W \to j_2^{-1} \otimes L_x \to 0.
\]

and $W$ contains $j_2$ also. The existence of a nonzero homomorphism $j_2 \to j_2^{-1} \otimes L_x$ implies that $j_1 \otimes j_2 = L_x \otimes L_y^{-1}$ for some $y \in X$. This proves that there are (if at all) only finitely many solutions for $x$ and $y$. If $(x, y)$ is one such, then $E$ has to be in the kernel of the map $H^1(j_2^* \otimes L_x^{-1}) \to H^1(j_1^* \otimes L_x^{-1} \otimes L_y)$ which is at most $1$-dimensional. Thus $W$ is uniquely determined by such a choice of $x$ and $y$. This proves our first assertion.

Now let $W \in P(D_j) \cap P(D_{j^{-1}})$, $j_2 \neq 1$. As above, we see that $W$ is the unique bundle given by the kernel of $H^1(X, j_2^* \otimes L_x^{-1}) \to H^1(X, j_2^*)$. Clearly, this is the kernel defined in Lemma 6.1. It remains to prove the transversality of the intersection of
$P(D_j)$ and $P(D_{j-1})$. Now $W$ is given simultaneously by two exact sequences

$$0 \to j \to W \to j^{-1} \otimes L_x \to 0$$

and

$$0 \to j^{-1} \to W \to j \otimes L_x \to 0.$$ 

Consider the map $j \oplus j^{-1} \to W$. Since $j \neq j^{-1}$, this map is a generic isomorphism and hence fits in an exact sequence

$$0 \to j \oplus j^{-1} \to W \to \mathcal{O}_x \to 0.$$ 

Let $M \subset \text{Ad}W$ be the bundle of endomorphisms (with trace 0) of $W$ taking $j$ into $j^{-1}$. Then we have the exact sequence

$$0 \to M \to \text{Ad}W \to L_x \to 0. \quad (6.20)$$ 

On the other hand, both $\text{Hom}(j^{-1} \otimes L_x, j) = j^2 \otimes L_x^{-1}$ and $\text{Hom}(j \otimes L_x, j^{-1}) = j^{-2} \otimes L_x^{-1}$ are clearly subbundles of $M$. At any $y \neq x$, we have $W_y = j_y \oplus j^{-1}_y$ and these two subspaces of $M_y$ may be represented in matrix form by $\begin{pmatrix} 0 & 0 \\ * & 0 \end{pmatrix}$ and $\begin{pmatrix} 0 & * \\ 0 & 0 \end{pmatrix}$ and hence are linearly independent. In other words, the map $j^2 \otimes L_x^{-1} \oplus j^{-2} \otimes L_x^{-1} \to M$ fails to be of maximal rank only at $x$. Since $\det M = L_x^{-1}$, we have the exact sequence

$$0 \to j^2 \otimes L_x^{-1} \oplus j^{-2} \otimes L_x^{-1} \to M \to \mathcal{O}_x \to 0.$$ 

In particular, the natural map $H^1(j^2 \otimes L_x^{-1}) \oplus H^1(j^{-2} \otimes L_x^{-1}) \to H^1(M)$ is surjective. From (6.20), we conclude that the map $H^1(M) \to H^1(\text{Ad}W)$ has as cokernel $H^1(X, L_x)$ which is of dimension $(g - 1)$. Thus the images of $H^1(j^2 \otimes L_x^{-1}), H^1(j^{-2} \otimes L_x^{-1})$ in $H^1(\text{Ad}W)$ by the natural inclusions have sum of dimension $(2g - 2)$. But the image of $H^1(j^2 \otimes L_x^{-1})$ in $H^1(\text{Ad}W)$ is the tangent space at $W$ to the cycle $P(W_x^*)$ in $U_x$. This proves the transversality, since $\dim U_x = 3g - 3$. \qed
Lemma 6.21. Let \( j \in J \) with \( j^2 \neq 1 \). Then identifying \( X \) with the intersection of \( P(D_j) \) and \( P(D_{j^{-1}}) \), we have the exact sequence

\[
0 \to T_{\pi j} \oplus T_{\pi j^{-1}} \to T_{\det}|X \to F \to 0
\]

where \( T_{\pi j} \) is the restriction to \( X \) of the tangent bundle along the fibres of \( P(D_j) \) and \( F \) is the quotient bundle associated to the canonical linear system on \( X \).

Proof. The exact sequence 6.20 when \( x \) is also varied, yields a sequence on \( X \times X \)

\[
0 \to M \to \text{Ad}W \to L_{\Delta} \to 0.
\]

Taking direct image on \( X \), we get

\[
R^1(p_1)_*M \to T_{\det}|X \to F \to 0.
\]

On the other hand, the map \( R^1(p_1)_*(j^2 \otimes L_{\Delta}^{-1}) \oplus R^1(p_1)_*(j^{-2} \otimes L_{\Delta}^{-1}) \to R^1(p_1)_*M \) has been proved to be surjective. As in Proposition 6.19 we see that the image of \( R^1(p_1)_*(j^2 \otimes L_{\Delta}^{-1}) \) is \( T_{\pi j} \), proving our assertion. \( \square \)

Lemma 6.22. (i) If \( j^2 \neq 1 \), then we have the exact sequence on \( P(D_j) \):

\[
0 \to H^1(X, \mathcal{O})_{P(D_j)} \to N_{P(D_j), U_X} \to \tau^{-1} \otimes \pi^*F(j) \to 0
\]

where \( F(j) \) is the quotient sheaf defined by the linear system \( K \otimes j^2 \).

(ii) If \( j^2 = 1 \), then we have the exact sequence on \( P(D_j) = X \times P \) with \( P = PH^1(X, \mathcal{O}) \)

\[
0 \to \text{Im} \, d\theta_E|P(D_j) \to T_{\det}|P(D_j) \to \tau^{-1} \otimes \pi^*F \to 0
\]
where $F$ is the quotient bundle on $X$ defined by the canonical linear system. Moreover, we have a commutative diagram on $P(D_j)$:

$$
\begin{array}{c}
0 \longrightarrow \tau \otimes H^1(X, \mathcal{O}) \longrightarrow F' \otimes H^1(X, \mathcal{O}) \longrightarrow H^1(X, \mathcal{O}) \longrightarrow 0 \\
0 \longrightarrow p_2^* T_p \longrightarrow \text{Im } d\theta_E \longrightarrow \tau^{-1} \otimes p_2^* T_p \longrightarrow 0
\end{array}
$$

where the extreme vertical maps are the natural ones and the first extension is obtained by tensoring the universal extension on $X \times P$ with $H^1(X, \mathcal{O})$.

**Proof.**  
(i) This follows from the sequence (6.9) and its direct image sequence noting that since $X \times j \not\subset C$ by Lemma 6.3 ii) and Proposition 6.8 the map $T_{p_1 \circ \pi} \to T_{U_X}$ restricted to $P(D_j)$ is still (sheaf theoretically) injective. The cokernel is clearly the tensor product of $\tau^{-1}$ and the sheaf $R^1(p_1)_*(p_2^* j^{-2} \otimes L_\Delta)$. From the exact sequence associated to

$$
0 \to p_2^* j^{-2} \to p_2^* j^{-2} \otimes L_\Delta \to j^{-2} \otimes K^*_X \to 0
$$

we identify this sheaf with $F(j)$.

(ii) This is an immediate consequence of Propositions 6.15 and 6.11.

**Corollary 6.23.** For any $j \in J$, we have

$$
K^*_{\text{det}}|P(D_j) \simeq \tau^2 \otimes \pi^* (j^4 \otimes K).
$$

**Proof.** From the exact sequence

$$
0 \to K^* \otimes j^{-2} \to H^1(X, j^{-2})_X \to F(j) \to 0
$$

we see that $\text{det } F(j) = K \otimes j^2$ and now from Lemma 6.22 i) we get $\text{det } T_{\text{det}}|P(D_j) = \tau^{-(g-2)} \otimes \text{det } F(j) \otimes \text{det } T_\pi = \tau^{-(g-2)} \otimes K \otimes j^2 \otimes \tau^8 \otimes j^2 = \tau^2 \otimes j^4 \otimes K$, as claimed. The case $j^2 = 1$ follows similarly from 6.22 ii).
7 Limits of good Hecke cycles

In this article, we study the limits of good Hecke cycles and their normal bundles in $U_X$. We first wish to fix an ample line bundle $\mathcal{O}(1)$ on $U_X$.

Lemma 7.1. If $K_{\text{det}}$ denotes the canonical line bundle along the fibres of the fibration $\det : U_X \to X$, then the line bundle $\mathcal{O}(1) = K_{\text{det}}^* \otimes (\det)^* K_X$ is an ample bundle on $U_X$.

Proof. Fix $\alpha \in J^1$. Consider the map $f : J \to J^1$ given by $f(j) = j^2 \otimes \alpha$. Then we have a commutative diagram

$$
\begin{array}{ccc}
    f^* U(2, 1) & \longrightarrow & U(2, 1) \\
    \downarrow & & \downarrow \\
    J & \underset{f}{\longrightarrow} & J^1
\end{array}
$$

Now $f^*(U(2, 1)) \to J$ is isomorphic to the product $U(2, \alpha) \times J \to J$. This gives in turn a commutative diagram

$$
\begin{array}{ccc}
    U(2, \alpha) \times \tilde{X} & \longrightarrow & U_X \\
    \downarrow & & \downarrow \\
    \tilde{X} = f^{-1}(X) & \underset{f}{\longrightarrow} & X
\end{array}
$$

Since $f$ is étale surjective, $X$ is nonsingular and $f^* K_X = K_X$. On the other hand, $f^* K_{\text{det}} \cong p_1^* K_{U_\alpha}$, so that our assertion follows from [2, Proposition 4.4] and the ampleness of $K^*$ on $U_\alpha$ (See [6, Theorem 1]) and of $K$ on $X$. □

Lemma 7.2. Let $Z$ be a good Hecke cycle. Then the polynomial $P(m, n) = \chi(Z, K_{\text{det}}^{-m} \otimes d\pi^* K_X^n)$ is given by $(4m + 1)(2m + 2n - 1) \times (g - 1)$. In particular, the Hilbert polynomial of a good Hecke cycle (with respect to $\mathcal{O}(1)$) is $P(n) = (4n + 1)(4n - 1)(g - 1)$. 

326
Proof. If \( W \) is the vector bundle to which the Hecke cycle \( Z \) corresponds, then by 5.16, we have

\[
(K_{\text{det}}^{-m} \otimes \det^* K^n_X)|_Z \simeq K_{\pi}^{-2m} \otimes \pi^* K^{m+n}_X.
\]

Now

\[
\pi_*(K_{\pi}^{-2m} \otimes \pi^* K^{m+n}_X) \simeq (\det W)^{2m} \otimes S^{4m}(W^*) \otimes K^{m+n}_X.
\]

Since the higher direct images are zero for \( m \geq 0 \), we have

\[
P(m, n) = \chi(X, (\det W)^{2m} \otimes S^{4m}(W^*) \otimes K^{m+n}_X)
\]

and the latter is computed to be as claimed, using the Riemann-Roch theorem.

\[\square\]

Let \( p : H \to U_X \) be the restriction of the dual Poincaré bundle on \( X \times U_X \) to \( U_X \) considered as a divisor by the map \( (\det, \text{Id}) \). By 5.2, v) and Lemma 5.5, we obtain a map \( h : H \to U_0 \) which is a projective fibration over the set of stable points of \( U_0 \) by 5.2 iv) and Lemma 5.14. The morphism \( \theta_E : P(D) \to U_X \) (in the notation of §6) lifts to a map \( \widetilde{\theta}_E : P(D) \to H \) since \( \theta^*_E H \simeq P(E)^* \) and \( E^* \) has a natural line subbundle by construction. Let \( \mathcal{K} \) be the variety of nonstable points of \( U_0 \), namely the Kummer variety \( \mathcal{K} = J/i \), where \( i \) is the involution \( j \mapsto j^{-1} \).

**Lemma 7.3.** We have a commutative diagram

\[
\begin{array}{ccc}
P(D) & \xrightarrow{\theta_E} & h^{-1}(\mathcal{K}) \subset H \\
\downarrow{p_2 \circ \pi} & & \downarrow{h} \\
J & \longrightarrow & \mathcal{K}
\end{array}
\]

Moreover \( \widetilde{\theta}_E \) is onto \( h^{-1}(\mathcal{K}) \).

**Proof.** A point of \( P(D) \) is represented by an exact sequence

\[
0 \to j \to E \to j^{-1} \otimes L_X \to 0
\]
Its image in $H$ is given by the element $E \in U_X$ and the one-dimensional space of linear forms on $E_x$ vanishing on $j_x$. Now the construction $K$ on $H$ which defines the morphism $h$ associates to it the bundle $F$ obtained by

$$0 \to F \to E \to \mathcal{O}_X \to 0$$

given by the above linear form. It is obvious $j$ is a subbundle of $F$ and hence $F$ is $S$-equivalent to $j \oplus j^{-1}$ proving the commutativity of the diagram. Now a point of $h^{-1}(\mathcal{X})$ is given by a stable bundle $E \in U_X$, for some $x \in X$, and a linear form on $E_x$ such that the bundle $F$ defined by the sequence

$$0 \to F \to E \to \mathcal{O}_X \to 0$$

is non-stable. Let $j \subset F$. Clearly then $j$ is also contained in $E$, for otherwise some line bundle of the form $j \otimes L_D, D > 0$ will be contained in $E$ contradicting its stability. Thus $E$ can be written as an extension

$$0 \to j \to E \to j^{-1} \otimes L_x \to 0$$

proving the lemma.

\[\square\]

**Lemma 7.4.** (i) If $k \in \mathcal{X}$ is not a node, then the reduced fibre of $h$ over $k$ is the push-out of $P(D_j)$ and $P(D_{j^{-1}})$ along the natural section $X$, where $j, j^{-1}$ are points in $J$ over $k$.

(ii) If $k \in \mathcal{X}$ is the image of an element $j \in J$ of order 2, then the reduced fibre of $h$ over $k$ is $X \times P$ where $P = PH^1(X, \mathcal{O})$. Moreover the schematic fibre of $h$ contains as a subscheme $X \times P_t$ where $P_t$ is the thickening of $P$ by $0 \to Q^* \to \mathcal{F} \to \Omega^1_P \to 0$, where $Q$ is the universal, quotient bundle of $P$.

**Proof.** (i) follows from diagram [7.3] and the fact that images by $\hat{\theta}_E$ of $(P(D_j))$ and $P(D_{j^{-1}})$ intersect transversally along $X$ since transversatility is true of $\theta_E$ (Lemma [6.19]).
(ii) Clearly the total thickening $Z$ of $P(D_j)$ in $P(D)$ is in the fibre over $k$ of the morphism $h \circ \tilde{\theta}_E$. Thus we have only to check that $\theta_E$ induces an epimorphism of $Z$ onto $X \times P_t$ and that the latter is a subscheme of $H$. But this follows from Remark 3.6.

\[\square\]

**Remark 7.5.** The reduced scheme defined in 7.4 (i) will be denoted $F_k$, if $k$ is not the image of an element of order 2. If it is, then $F_k$ will denote the subscheme $X \times PH^1(X, O)_t$ of $U_X$. These are contained in the fibres of $H \to U_0$. Probably, these are precisely the schematic fibres, and some of the technical difficulties in this article can be obviated if one could prove this directly.

**Lemma 7.6.** The natural morphism of the relative Hilbert scheme $\text{Hilb}(H, U_0, P(n))$ into $\text{Hilb}(U_X, P(n))$ is injective.

**Proof.** Since $P(n)$ is of degree 2 in $n$, any element of $\text{Hilb}(U_X, P(n))$ represents a subscheme of $U_X$ of dimension 2. Hence our assertion follows from Proposition 6.19. \[\square\]

Let $\text{Hilb}(H, U_0, P(m, n))$ be the relative Hilbert scheme of the map $H \to U_0$ of cycles $Z$ satisfying $\chi(Z, p^*(K_{\text{det}}^{-m} \otimes \text{det}^* K_X^n)) = P(m, n)$. If $H_2$ is the image of $\text{Hilb}(H, U_0, P(m, n))$ in $\text{Hilb}(U_X, P(n))$ then $H_2$ contains good Hecke cycles. Now if $Z \in H_2$ is not a good Hecke cycle, then $Z_{\text{red}} \subset F_k$ for a unique $k \in \mathcal{K}$. For a fixed $k \in \mathcal{K}$ the set of elements of $H_2$ which are contained set theoretically in $F_k$ is denoted $H_{2,k}$.

**7.7 Definition of The Varieties $Q_j, Q_{j^{-1}}, R_k$.**

Now we will define for $k$ not a node, three subvarieties $Q_j, Q_{j^{-1}}$ and $R_k$ (with $j, j^{-1} \in J$ lying over $k$) of $H_{2,k}$. Consider the Grassmannian of lines in $PH^1(X, j^2)$; the symmetric product of the projective line bundle over it will be denoted $Q_j$. Also, we denote by $R_k$ the product of $PH^1(X, j^2)$ and $P(H^1(X, j^{-2}))$ for $j$ lying over
$k \in \mathcal{K}$. Now points of $Q_j$, $Q_{j-1}$ and $R_k$ can be considered as subschemes of $F_k$. In fact, consider the exact sequences

$$
0 \to j^2 \to D_j \to H^1(X, j^2)_X \to 0
$$

$$
0 \to j^{-2} \to D_{j-1} \to H^1(X, j^{-2})_X \to 0.
$$

Any line in $PH^1(X, j^2)$ gives rise to a plane subbundle of $P(D_j)$ over $X$. A point of $Q_j$ gives rise a pair of projective line subbundles (possibly identical) of this plane bundle. Thus we obtain a subscheme of $F_k$. Similarly a point of $R_k$ gives rise to projective line subbundles of $P(D_j)$, $P(D_{j-1})$ containing the sections of $P(D_j)$, $P(D_{j-1})$ given by $j^2$ and $j^{-2}$ respectively. To compute the Hilbert polynomials of these schemes, we may assume without loss of generality that the scheme is obtained by gluing two projective line bundles $P(F_1)$, $P(F_2)$ on $X$ where $F_1$ and $F_2$ are of degree zero and contain either $j^2$ or $j^{-2}$ as line subbundles, along the sections given by these subbundles. Now, from Corollary 6.22 it follows that $\mathcal{O}(1)$ restricts to $P(D_j)$ as $K_X^2 \otimes j^4 \otimes \tau^2$. Its restriction to the section of $P(D_j)$ is therefore seen to be $K_X^2$. Hence the Hilbert polynomial of the subschemes corresponding to points of $Q_j$, $R_k$ is, on using the Mayer-Vietoris sequence,

$$
2\chi(X, K_X^{m+n} \otimes S^{2m}(F^*)) - \chi(X, K_X^{m+n}) = (4m+1)(2m+2n-1)(g-1).
$$

Thus, we have identified the sets $Q_j$, $Q_{j-1}$, $R_k$ with subsets of $H_{2,k}$.

If $k$ is a node, $Q_k$ is defined to be the variety of subschemes of the form $X \times C$, where $C$ is a conic in $P = PH^1(X, \mathcal{O})$, while $R_k$ denotes those of the form $X \times C$ where $C$ is a line thickened by $\tau^{-1}$ contained in $P_t$ but not in $P$. As above $Q_k$, $R_k$ are checked to be subsets of $H_{2,k}$.

**Proposition 7.8.** If $k$ is not a node of $\mathcal{K}$, and $j$, $j^{-1} \in J$ are points over $k$, then $H_{2,k} = Q_j \cup Q_{j-1} \cup R_k$. If $k$ is a node of $\mathcal{K}$, then $H_{2,k} = Q_k \cup R_k$.

The rest of this section will be devoted to the proof of Proposition 7.8.
Lemma 7.9. If $Z \in H_2$, then the map $p : Z \to X$ is surjective and for generic $x \in X$, the fibre $Z_x$ has $(2m + 1)$ as the Hilbert polynomial with respect to the ample generator $h$ of $\text{Pic } U_x$.

Proof. Since the polynomial $P(m, n)$ is not independent of $n$, it follows that the map $p : Z \to X$ is surjective. For large $m$, we have

$$P(m, n) = \chi(X, p^*(K_{\det}^{-m}) \otimes K_X^n).$$

In other words, $P(m, n)$ is the Hilbert polynomial of $p^*(K_{\det}^{-m})$ with respect to the ample line bundle $K_X$ on $X$. Hence the rank of the sheaf $p^*(K_{\det}^{-m})$ is $\frac{1}{\deg K}$ (the coefficient of $n$ in $P(m, n)$), namely

$$\frac{1}{2g - 2}(8m + 2)(g - 1) = 4m + 1.$$ But $K_{\det}$ restricts to $U_x$ as $K_{U_x}^*$, which is twice the ample generator of $\text{Pic } U_x$. Hence the lemma. □

Lemma 7.10. Let $S$ be a subscheme of $U_x$ having $2m + 1$ as Hilbert polynomial. If $S_{\text{red}} \subset (F_k)_{\text{red}}$, for some $k \in \mathscr{H}$, then $S$ is a conic contained schematically in $F_k$.

Remark 7.11. The proof of Lemma 7.10 given below can be simplified if one knew a priori that $h|S$ is very ample. This would follow for instance if we could show that $h$ itself is very ample which is very likely to be true and indeed so at least if $X$ is hyperelliptic [11 5.10, II]. However, since the irreducible components of $(F_k)_{\text{red}} \cap U_x$ are projective spaces, the restriction of $h$ to these is very ample, as ample bundles on a projective space are very ample. From this it is easy to see that $h|(F_k)_{\text{red}} \cap U_x$ is very ample and hence $h|S_{\text{red}}$ is very ample. This fact will be used in the proof.

Proof of Lemma 7.10. Let $S$ be a subscheme of $U_x$ having $2m + 1$ as Hilbert polynomial. If $S$ is reduced, our assertion follows from Lemma 4.2 and Remark 4.4. If $S$ is not reduced, we shall use Lemma 4.3. Let $S'$ be the thickening of $S_{\text{red}} = \mathbb{P}^1$ by the line
bundle $L$ mentioned in that lemma. We first show that $\deg L \geq -1$. Since $S'$ is a subscheme of $U_x$, the bundle $L$ is a quotient of the conormal bundle of $S_{\text{red}}$ in $U_x$. Now we have the exact sequences (Lemma \[6.21\])

$$0 \to \tau \otimes \text{trivial} \to N_{P(D)(j,x),U_x}^* \to \text{trivial} \to 0$$

and

$$0 \to \tau \otimes \text{trivial} \to N_{P(D)(j,x),U_x}^* \to \tau \otimes \Omega^1 \to 0$$

according as $j^2 \neq 1$ or $j^2 = 1$. On the other hand, we have the exact sequence

$$0 \to N_{P(D)(j,x),U_x}^* \to N_{P^1, U_x}^* \to \tau^{-1} \otimes \text{trivial} \to 0.$$ 

Since $\tau \otimes \Omega^1$ restricts to $P^1$ as $\tau^{-1} \oplus \text{trivial}$, it follows that any quotient line bundle of $N_{P^1, U_x}^*$ is of deg $\geq -1$. Now if $j^2 \neq 1$, any quotient of $N_{P^1, U_x}^*$ isomorphic to $\tau^{-1}$ is actually a quotient of $N_{P^1, P(D)(j,x)}^*$ so that $S \subset P(D)(j,x)$. If $j^2 = 1$, we similarly conclude that $S \subset F_k = PH^1(X, \mathcal{O})$. This proves the lemma.

**Lemma 7.12.** If $Z \in H_{2,k}$, then the morphism $p : Z \to X$ is flat.

**Proof.** Using generic flatness, we see that on an open subset of $X$, $p$ itself defines a section of a suitable relative Hilbert scheme for the morphism $Z \to X$. This extends to a section over the whole of $X$ and thus gives a closed subscheme $Z'$ of $Z$ flat over $X$. Now from Lemma \[7.9\] it follows that all the fibres $Z'_x$ of $Z'$ have Hilbert polynomial $2m+1$ with respect to $h$. Now by Lemma \[7.10\] it follows that $Z'_x \subset F_k$ for each $x \in X$. Since the map $p : Z' \to X$ is flat, it follows that $Z' \subset F_k$. Now suppose we show that $K_{det}^m | F_k$ has a direct image $V$ on $X$ of the form $K_{X}^{4m} \otimes (a \text{ stable vector bundle of degree } 0)$, at least for large $m$. Then we would have $p_*(K_{det}^m | Z')$ is a quotient of $V$ for large $m$ and hence would be a vector bundle of rank $4m + 1$ and degree $\geq 2m(g - 1)(4m + 1)$. Hence

$$\chi(Z', K_{det}^m \otimes p^* K_{X}^m) = \chi(X, p^*(K_{det}^m) \otimes K_{X}^n)$$
by Riemann-Roch theorem. On the other hand, if $I$ is the sheaf of ideals defining $Z'$ in $Z$, then from the exact sequence
\[ 0 \to I \to \mathcal{O}_Z \to \mathcal{O}_{Z'} \to 0, \]
we conclude that $\chi(Z, \mathcal{O}(n)) \geq \chi(Z', \mathcal{O}(n))$ for large $n$, and that equality holds only if $Z = Z'$. It remains to prove

**Lemma 7.13.** The direct image of $K^m_{\text{det}}|F_k$ on $X$ is of the form $K^m_X \otimes (a \text{ semistable vector bundle of degree 0})$.

**Proof.** First assume that $k$ is not a node. Then $F_k = P(D)_j \cup P(D)_{j-1}$ with $P(D)_j \cap (PD)_{j-1} = X$. The restriction of $K_{\text{det}}$ to $P(D)_j$ (resp. $X$) is isomorphic to $K_X \otimes j^4 \otimes \tau^2_{D_j}$ (resp. $K_X$) (Corollary 6.22). Now the direct image of $j^4 \otimes \tau^2_{D_j}$ is isomorphic to $j^4 \otimes S^2(D^*_j)$, and the restriction map to the direct image of $j^4 \otimes \tau^2_{D_j}$ on $X$ (namely, the trivial bundle) is induced by the natural map $S^2(D^*) \to j^{-4}$, given by the inclusion $j^2 \to D_j$. Hence, by the Mayer-Vietoris sequence, we see that $p^*(K^m_{\text{det}}|F_k)$ is the tensor product of $K^m_X$ and the fibre product of $j^4m \otimes S^2m(D^*_j)$ and $j^{-4m} \otimes S^2m(D^*_j)$ over the trivial bundle. Since $S^2m(D^*_j)$ is obtainable (6.1) as successive extension of line bundles of degree 0, it is semistable of degree 0. Hence so is the fibre product mentioned above proving Lemma 7.13 in this case.

Now let $k$ be a node. Then we have $\text{Pic}(X \times PH^1(X, \mathcal{O})) \to \text{Pic}(X \times PH^1(X, \mathcal{O}))$ is an isomorphism. In particular from 6.22 we see that the restriction of $K^m_{\text{det}}$ to $X \times PH^1(X, \mathcal{O})$ is of the form $K^m_X \otimes a \text{ line bundle coming from } PH^1(X, \mathcal{O})$. Hence its direct image is of the form $K^m_X \otimes a \text{ trivial bundle}$, completing the proof of Lemma 7.13.

**Proof of Proposition 7.9.** Let $Z \in H_{2,k}$. By lemma 7.12 the map $p : Z \to X$ is flat, and by Lemma 7.10 $Z$ is schematically
contained in $F_k$ and all the fibres are conics. Let us first consider the case when $Z$ is a subscheme of $P(D)_j$ for some $j$ over $k$. By (4.4 iv) there exists a vector subbundle $E$ of $D_j$ of rank 3, such that $Z \subset P(E)$. Now $Z$ defines a divisor in $P(E)$ with $L_Z \cong \tau^2_E \otimes L$ for some line bundle $L$ on $X$. We have the exact sequence

$$0 \to \tau^{-2}_E \otimes L^* \otimes K^{-m}_{\det}|_{P(E)} \otimes K^n_X \to K^{-m}_{\det}|_{P(E)} \otimes K^n_X \to K^{-m}_{\det}|_Z \otimes K^n_X \to 0.$$  

Substituting $K^{-m}_{\det}|_{P(E)} \cong \tau^2_E \otimes K_X \otimes j^4$, and taking direct image on $X$, we obtain

$$\chi(Z, K^{-m}_{\det} \otimes K^n_X) = \chi(X, K^{m+n}_X \otimes S^{2m}(E^*)) - \chi(X, L^* \otimes K^{m+n}_X \otimes S^{2m-2}(E^*)).$$  

The right side can be computed in terms of the degrees of $L$ and $E$ by the Riemann-Roch theorem. But the left side is given to be $P(m, n) = (4m + 1)(2m + 2n - 1)(g - 1)$. Equating coefficients of these two polynomials, we check that deg $L = 0$ and deg $E = 0$. In other words, when $Z \subset P(D)_j$, we have shown that $Z$ is a divisor in $P(E)$ given by a nonzero quadratic form $E \to E^* \otimes L$, where $L$ is of degree 0 and $E$ a subbundle of $D_j$, also of degree 0. Now, if $k$ is a node, clearly $E$ is also trivial since $D_j$ is trivial in this case. Moreover the quadratic form is a nonzero section of $S^2(D^*_j) \otimes L$, with deg $L = 0$, and hence it follows (a) that $L$ is trivial and (b) that the quadratic form is a constant. Thus if $Z \subset P(D)_j$ with $j^2 = 1$, then $Z \in R_k$. On the other hand, if $k$ is not a node, by § 6.1, $E$ is the inverse image of a trivial vector subbundle of $H^1(X, j^2)_X$ of rank 2. Notice first that the map $E \to E^* \otimes L$ cannot be an isomorphism since $E^* \otimes L$ contains a direct sum of two line bundles of degree 0 while $E$ does not. Moreover the kernel of $E \to E^* \otimes L$ is a proper subbundle of degree 0 and, again by § 6.1, it must contain $j^2$. Thus the quadratic form on $E$ is induced by an $L$-valued quadratic form on the trivial subbundle $E/\mathcal{J} \subset H^1(X, j^2)_X$ viz. a nonzero section of $S^2((E/\mathcal{J})^*) \otimes L$. As before, since $L$ is of degree 0, it follows (a) that $L$ is trivial, and (b) that the section of $S^2(E/\mathcal{J})^*$ is constant. This proves that if $Z$ is contained in $P(D)_j$ then $Z \in Q_j$.  

333
It remains to consider the case when $Z \notin P(D)_j$ for any $j$ over $k$. Clearly if $k$ is not a node, $Z$ consists of two irreducible components $Z_1$ and $Z_2$ with $Z_1 \subset P(D)_j$, $Z_2 \subset P(D)_{j-1}$. Moreover, $Z_1$ (resp. $Z_2$) defines a subbundle $E_1$ (resp. $E_2$) of $D_j$ (resp. $D_{j-1}$) of rank 2, containing $j^2$ (resp. $j^{-2}$). Let their degrees be $d_1$, $d_2$. By the Mayer-Vietoris sequence, we see as before,

$$P(m, n) = \chi(Z, K_{\text{det}}^{-m} \otimes K_X^n) = \chi(X, S^{2m}(E_1^*) \otimes K_X^{m+n} \otimes j^{4m})$$

$$+ \chi(X, S^{2m}(E_2^*) \otimes K_X^{m+n} \otimes j^{-4m}) - \chi(X, K_X^{m+n}).$$

Computing the right side by the Riemann-Roch theorem, and substituting for $P(m, n)$, we obtain $d_1 = d_2 = 0$. Thus $E_1$, $E_2$ are inverse images of line subbundle of the trivial bundles $H^1(X, j^2)_X$, $H^1(X, j^{-2})_X$ and since these subbundles are of degree 0, they must themselves be trivial. In other words, $Z \in R_k$.

Finally let $k$ be a node and $Z \in H_{2,k}$, $Z \notin P(D)_j = (F_k)_{\text{red}}$. By 7.10, $Z \subset F_k$. In this case, $Z_{\text{red}}$ is projective bundle associated to a rank 2 vector subbundle $E$ of $D_j = H^1(X, \mathcal{O})_X$. Moreover $Z$ is given by thickening within $X \times F_k$ by a line bundle of the form $\tau^{-1}_E \otimes L$, where $L$ is a line bundle on $X$. From the exact sequence

$$0 \to \tau^{-1}_E \otimes L \to \mathcal{O}_Z \to \mathcal{O}_{Z_{\text{red}}} \to 0$$

and the fact that $K_{\text{det}}|X \times PH^1(X, \mathcal{O}) \simeq \tau^2 \otimes K_X$ we obtain

$$\chi(Z, K_{\text{det}}^{-m} \otimes K_X^n) = \chi(X, S^{2m}(E^*) \otimes K_X^{m+n})$$

$$+ \chi(X, S^{2m-1}(E^*) \otimes K_X^{m+n} \otimes L).$$

Equating this expression with $P(m, n)$, we obtain $\deg E = 0$, $\deg L = 0$. Since $E$ is contained in the trivial bundle $H^1(X, \mathcal{O})_X$, $E$ itself is trivial. Now we claim that if $L$ is nontrivial, $\text{Hom}(\tau_E \otimes L^{-1}, N_{X \times P(E), UX}) = 0$. This follows from sequence

$$0 \to N_{X \times P(E), X \times P} \to N_{X \times P(E), UX} \to N_{X \times P, UX \mid X \times P(E)} \to 0$$

and the sequences in 6.21 ii), since
\( H^0(\text{Hom}(\tau_E \otimes L^{-1}, N_{X \times P(E), X \times P})) = H^0(\text{Hom}(\tau_E \otimes L^{-1}, \tau \otimes \text{trivial})) = 0. \)

(b) \( H^0(\text{Hom}(\tau_E \otimes L^{-1}, \tau^{-1} \otimes F)) = 0. \)

c) \( H^0(\text{Hom}(\tau_E \otimes L^{-1}, \tau^{-1} \otimes T_P)) = 0, \) and

d) \( H^0(\text{Hom}(\tau_E \otimes L^{-1}, T_P)) = 0. \)

It follows that \( L \) is trivial, since \( \tau^{-1} \otimes L \subset N_{X \times P(E), U_X}. \) Thus the scheme \( Z \) is of the form \( X \times C, \) where \( C \) is a conic contained in \( P_t, \) and hence \( Z \in R_k. \) This completes the proof of Proposition 7.9.

\section*{8 Nonsingularity of the Hecke component}

We will now prove that \( H_0, \) the irreducible component of \( \text{Hilb}(U_X) \) containing Hecke cycles, is nonsingular. Since \( H_0 \) is a variety of dimension \( 3g - 3, \) it is enough to show that the Zariski tangent space at any point of \( H_0 \) is of dimension \( 3g - 3. \) This is done in Propositions 8.1, 8.5, 8.9, and 8.12. From the description in § 7 of the nature of the subschemes of \( U_X \) occurring in \( H_2 \) (and hence \( H_0 \)), it follows that all these schemes are local complete intersections and hence the Zariski tangent space at any \( Z \in H_0 \) to the Hilbert scheme itself is given by \( H^0(Z, N_{Z, U_X}) \) \[9a\]. Thus the nonsingularity of \( H_0 \) at some \( Z \in H_0 \) would follow if \( \dim H^0(Z, N_{Z, U_X}) \leq 3g - 3. \) However, it turns out that there are points in \( H_0 \) at which the Hilbert scheme itself is not smooth. We will first compute \( H^0(Z, N_{Z, U_X}) \) for \( Z \in H_0. \)

We have to discuss several cases.

**Proposition 8.1.** Let \( Z \in R_k, \) \( k \) not a node and \( Z \notin P(D)_j, \) for any \( j \) over \( k. \) Then the Hilbert scheme is smooth at \( Z. \)

The proof is completed in 8.4.

By the definition of \( R_k, \) there exist points \( p, p' \) in

\[ PH^1(X, j^2), \ P(H^1(X, j^{-2})) \]
such that if $E, E'$ are the inverse images in $D_j, D_{j-1}$ of the trivial line bundles corresponding to these two points, then $Z = P(E) \cap P(E')$. Recall also that $P(E) \cap P(E') = X$ imbedded in $P(D_j), P(D_{j-1})$ by means of the subbundles $J^2, J^{-1}$ of $D_j, D_{j-1}$ respectively.

**Lemma 8.2.** Let $U$ be a nonsingular variety and $l_1, l_2$ be nonsingular subvarieties intersecting (schematically) in a nonsingular subvariety $X$ which is a divisor in both $l_1$ and $l_2$.

(i) Then the reduced scheme $l = l_1 \cup l_2$ is a local complete intersection.

(ii) Moreover, we have the exact sequence

$$0 \to N^*_l, U \to \tilde{N}_1 \oplus \tilde{N}_2 \to N^*_l, U|X \to 0$$

where $N_1, N_2$ are the restrictions of $N^*_l, U$ to $l_1, l_2$ respectively.

(iii) $N_1$ fits in an exact sequence

$$0 \to N_1 \to N^*_l, U \to N^*_X, l_2 \to 0,$$

while

(iv) $N^*_l, U|X$ fits in the sequence

$$0 \to N^*_X, U/N^*_X, l_1, U \otimes N^*_X, l_2 \to N^*_l, U|X \to N^*_X, l_1 \otimes N^*_X, l_2 \to 0.$$

**Proof.** At any point of $l$, we can choose a regular system of parameters $(x_1, \ldots, x_r, y_1, y_2, z_1, \ldots, z_s)$ for $\mathcal{O}_U$ with $(x_1, \ldots, x_r, y_1) = I_1$ and $(x_1, \ldots, x_r, y_2) = I_2$ being the ideals defining $l_1, l_2$ respectively. Since $l$ is then defined by $I_1 \cap I_2 = (x_1, \ldots, x_r, y_1, y_2)$, it follows that $l$ is a complete intersection. The sequence (ii) is obtained by tensoring with $N^*_l, U$ the basic exact sequence

$$0 \to \mathcal{O}_l \to \mathcal{O}_{l_1} \oplus \mathcal{O}_{l_2} \to \mathcal{O}_X \to 0.$$
We have now the isomorphism $N_l = I_1 \cap I_2 / (I_1 \cap I_2)^2 \cong I_1 \cap I_2 / I_1(I_1 \cap I_2)$ and an exact sequence

$$0 \to I_1 \cap I_2 / I_1(I_1 \cap I_2) \to I_1 / I_1^2 \to I_1 / I_1^2 + I_1 \cap I_2 \to 0.$$ 

But

$$I_1 / I_1^2 + I_1 \cap I_2 \cong \frac{I_1 / I_1 \cap I_2}{(I_1 / I_1 \cap I_2)^2} \cong \frac{I_1 + I_2 / I_2}{(I_1 + I_2 / I_2)^2} \cong N_{X,l_2}^*$$

proving (iii).

Finally, restrict (iii) to $X$ to get the four term sequence

$$0 \to \text{Tor}_1^1 (N_{X,l_2}^*, \mathcal{O}_X) \to N_{l_1,U}^* |X \to N_{l_1,U}^* |X \to N_{X,l_2}^* \to 0.$$ 

From the resolution

$$0 \to L_{X}^{-1} \to \mathcal{O}_{l_1} \to \mathcal{O}_X \to 0$$

and the isomorphism $L_{X}^{-1} |X \cong N_{X,l_1}^*$, we evaluate the Tor-term to be $N_{X,l_2}^* \otimes N_{X,l_1}^*$. On the other hand, it is clear that $N_{l_1,U}^* |X \to N_{X,l_2}^*$ has kernel $\cong (N_{X,U} / N_{X,l_1} \otimes N_{X,l_2})^*$. Dualising, we obtain (iv). □

We will apply 8.2 to the case $U = U_X$, $l_1 = P(E)$, $l_2 = P(E')$ and $X = l_1 \cap l_2$. In this case we have $N_{X,l_2} \cong \text{Hom}(j^{-2}, \mathcal{O}) = j^2$ from the exact sequence

$$0 \to j^{-2} \to E' \to \mathcal{O} \to 0.$$ 

From the definition of $N_1$, we get

$$\det N_1 \cong \det N_{l_1,U_X}^* \otimes (\det \tilde{N}_{X,l_2}^*)^{-1}.$$ 

But $\det \tilde{N}_{X,l_2}^* \cong L_X$, where $L_X$ is the line bundle on $l_1$ associated to the divisor $X$, as is seen from the fact that the bundle $j^{-2}$ on $X$ extends to $l_1$ and from the resolution

$$0 \to L_{X}^{-1} \to \mathcal{O}_{l_1} \to \mathcal{O}_X \to 0$$
for the sheaf $\mathcal{O}_X$ on $l_1$. But $L_X$ is easily seen to be $\tau_E$. Thus if

$$\omega^j$$

is the dualising sheaf on $l$, we get $\omega_l|_{l_1} \simeq \omega_{U_X} \otimes \det N^*_{l_1} \simeq \omega_{U_X} \otimes \det N_{l_1,U_X} \otimes (\det N^*_{X,l_2}) \simeq \omega_{l_1} \otimes \tau_E$. But $\omega_{l_1} \simeq K_X \otimes K_\pi$, where $K_\pi$ is the canonical bundle along the fibres of $P(E) \to X$ and hence $\simeq \tau^{-2}_E \otimes \det E^* \simeq \tau^{-2}_E \otimes j^{-2}$. This proves

**Lemma 8.3.** The dualising sheaf $\omega_l$ of $l = l_1 \cup l_2$ restricts to $l_1$ as $\tau^{-1}_E \otimes j^2 \otimes K_X$. In particular, $\omega_l|_X \simeq K_X$.

**Proof of Proposition 8.1.** We wish to compute $H^2(l, \omega_l \otimes N^*_{l,U_X})$ which is dual to the space $H^0(l, N_{l,U_X})$ required. To this end we first compute $H^2(l_1, \omega_l \otimes N_l)$. From the exact sequence $0 \to N_1 \to N^*_{l_1,U_X} \to j^{-2} \to 0$, we obtain $H^2(l_1, \omega_l \otimes N_1) \simeq H^2(l_1, \omega_l \otimes N^*_{l_1,U_X})$ since $H^i(X, K_X \otimes j^{-2}) = 0$ for $i = 1, 2$. But $H^2(l_1, \omega_l \otimes N^*_{l_1,U_X}) = H^2(l_1, \omega_l \otimes \tau \otimes N^*_{l_1,U_X})$ by Lemma 8.3 which in turn is dual to $H^2(l_1, \tau^{-1} \otimes N_{l_1,U_X})$. To compute this, we use the exact sequence

$$0 \to N_{l_1,P(D_j)} \to N_{l_1,U_X} \to N_{P(D_j), U_X|l_1} \to 0$$

and observe that $N_{l_1,P(D_j)} \simeq \tau \otimes V'$, where $V'$ is a vector space of rank $(g - 2)$. Hence $\dim H^0(l_1, \tau^{-1} \otimes N_{l_1,P(D_j)}) = g - 2$. To compute $H^0(l_1, \tau^{-1} \otimes N_{P(D_j), U_X})$, we appeal to Lemma 6.22 (1). Since $H^0(l_1, \tau^{-1} \otimes H^1(X, \mathcal{O}_X)) = 0$ and $H^0(l_1, \tau^{-2} \otimes \pi^* F(j))$ is also seen to be zero, we get $H^0(l_1, \tau^{-1} \otimes N_{P(D_j), U_X}) = 0$ and hence $\dim H^2(l_1, \omega_l \otimes N_1) = g - 2$. Now Proposition 8.1 will follow from the exact sequence in 8.2 tensored with $\omega_l$, if we prove

**Lemma 8.4.** $\dim H^1(X, N^*_{l,U_X} \otimes \omega_l) \leq g + 1$.

**Proof.** Since $\omega_l|_X \simeq K_X$ by Lemma 8.3, we have only to show by duality, that $\dim H^0(X, N_{l,U_X}) \leq g + 1$. For this, we will use Lemma 8.2 (iv). In fact, $N_{X,l_1} \simeq j^{-2}$ and $N_{X,l_2} \simeq j^2$ and hence $H^0(X, N_{X,l_2} \otimes N_{X,l_2})$ is of dimension 1. To compute

$$H^0(X, N_{X,U_X}/N_{X,l_1} \otimes N_{X,l_2})$$

we use the exact sequence in 6.21 namely

$$0 \to N_{X,P(D_j)} \oplus N_{X,P(D_{j-1})} \to N_{X,U_X} \to F \to 0.$$
Thus we get
\[ 0 \to (N_{l_1, P(D_j)} \oplus N_{l_2, P(D_{j-1})})|X \to N_{X, U_X/N_{X,l_1} \oplus N_{X,l_2}} \to F \to 0. \]

But \( N_{l_1, P(D_j)}|X \simeq \tau \otimes (D_j/l_1)|X \simeq j^{-2} \otimes \text{trivial.} \) Hence \( H^0 \) of the first term above is zero while \( H^0(X, F) \) is clearly of dimension \( g. \) This proves Lemma 8.4, and hence completes the proof of Proposition 8.1. □

**Proposition 8.5.** Let \( Z \in Q_k, k \) a node. Assume that \( Z = X \times C, \) where \( C \) is a conic in \( P = PH^1(X, \theta). \) Then \( \dim H^0(Z, N_{Z,U_X}) \leq 3g - 3, 3g - 2 \) or \( 3g - 1 \) according as \( C \) is nondegenerate, is a pair of intersecting lines, or is a double line. In particular, if \( C \) is nondegenerate, the Hilbert scheme is smooth at \( Z. \)

**Proof.** We first recall [9, SGA 6, VII, Proposition 1.7] that if \( X_1 \subset X_2 \subset X_3 \) with \( X_2, X_3 \) smooth and \( X_1 \) a local complete intersection, then by pushing out the restriction to \( X_1 \) of the exact sequence
\[ 0 \to T_{X_2} \to T_{X_3}|X_2 \to N_{X_2,X_3} \to 0 \]
by means of the map \( T_{X_2}|X_1 \to N_{X_1,X_2}, \) we obtain the exact sequence
\[ 0 \to N_{X_1,X_2} \to X_{X_1,X_3} \to N_{X_2,X_3}|X_1 \to 0. \]

We wish to apply this to the case \( X_1 = Z, X_2 = X \times P \) and \( X_3 = U_X, \) and use the description of \( T_{U_X}|X \times P \) given in 6.22 (ii). Then we see that \( N_{Z,U_X} \) fits in exact sequence
\[ 0 \to N' \to N_{Z,U_X} \to \tau^{-1} \otimes F|Z \to 0 \]
(8.6)
where \( N' \) is obtained as the push-out of the sequence
\[ 0 \to T_P|Z \to \text{Im} \, d\theta_E|Z \to \tau^{-1} \otimes T_P|Z \to 0 \]
by means of the map \( T_P|Z \to N_{Z,X \times P} = N_{C,P}. \) Since the direct image of \( \tau^{-1} \otimes F|Z \) on \( X \) is zero, it follows that \( H^0(Z, \tau^{-1} \otimes F) = \)
0 and hence that $H^0(Z, N') \to H^0(Z, N_{Z,U_X})$ is an isomorphism. Again by \[6.22\](ii), we have the commutative diagram (on $Z$)

$$
\begin{array}{cccccc}
0 & \to & \tau \otimes H^1(X, \mathcal{O}) & \to & F' \otimes H^1(X, \mathcal{O}) & \to & H^1(X, \mathcal{O})_Z & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \to & N_{C,P} & \to & N' & \to & \tau^{-1} \otimes T_P & \to & 0
\end{array}
$$

(8.7)

where the top sequence is obtained by tensoring the universal extension $F'$ on $X \times P$ with $H^1(X, \mathcal{O})$. Now $H^0(N_{C,P})$ is easily computed to be $3g - 4$, for instance by imbedding $C$ as a divisor in a plane $\mathcal{O}$ and proving $\dim H^0(C, N_{C,\mathcal{O}}) = 5$ and $\dim H^0(C, N_{\tilde{\omega}P}) = 3(g - 3)$. It remains therefore to compute the kernel of the boundary homomorphism $H^0(X \times C, \tau^{-1} \otimes T_P) \to H^1(X \times C, N_{C,P})$. But now it is easy to see that $H^0(P, \tau^{-1} \otimes T_P) \to H^0(C, \tau^{-1} \otimes T_P)$ is surjective by checking $H^0(P, \tau^{-1} \otimes T_P) \to H^0(\mathcal{O}, \tau^{-1} \otimes T_P)$ and $H^0(\mathcal{O}, \tau^{-1} \otimes T_P) \to H^0(C, \tau^{-1} \otimes T_P)$ are both surjective. Thus from (8.7), we see that the required boundary homomorphism is the composite of that of the top sequence $H^1(X, \mathcal{O}) \to H^1(X \times P, H^1(X, \mathcal{O}) \otimes \tau)$ and the natural map $H^1(X \times P, H^1(X, \mathcal{O}) \otimes \tau) \to H^1(C, N_{C,P})$. Again we have the diagram (on $Z$).

$$
\begin{array}{cccccc}
0 & \to & \tau \otimes H^1(X, \mathcal{O}) & \to & F' \otimes H^1(X, \mathcal{O}) & \to & H^1(X, \mathcal{O})_Z & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \to & N_{C,P} & \to & F' \otimes \tau^{-1} \otimes N_{C,P} & \to & \tau^{-1} \otimes N_{C,P} & \to & 0
\end{array}
$$

(8.8)

where the lower sequence is obtained as the tensor product on $X \times C$ of the universal extension $F'$ by $\tau^{-1} \otimes N_{C,P}$. From (8.8) we conclude that the required map is the composite of the natural map $H^0(C, \tau^{-1} \otimes T_P) \to H^0(C, \tau^{-1} \otimes N_{C,P})$ and the boundary homomorphism $H^0(C, \tau^{-1} \otimes N_{C,P}) \to H^1(X \times C, N_{C,P})$. From the definition of the universal extension, we conclude that the latter map is injective. Thus finally we have

$$
\dim H^0(X \times C, N_{Z,U_X}) = \dim H^0(X \times C, N')
$$

so that Proposition 8.5 would follow from □

**Lemma 8.9.** If $C$ is a conic in a projective space $P$, then

$$
\ker H^0(C, \tau^{-1} \otimes T_P) \to H^0(C, \tau^{-1} \otimes N_{C,P})
$$

is of dimension 1, 2, or 3 according as $C$ is nondegenerate, is a pair of lines, or is a double line.

**Proof.** By duality, and noting that $\tau^{-1}|C$ is the dualising sheaf, we have to compute the dimension of the cokernel of $H^1(C, N^*_{C,P}) \to H^1(C, \Omega^1_P)$. From the exact sequence

$$
N^*_{C,P} \to \Omega^1_p|C \to \Omega^1_C \to 0
$$

we see that this cokernel is isomorphic to $H^1(C, \Omega^1_C)$ since $H^2(C, \mathcal{F}) = 0$ for any coherent sheaf $\mathcal{F}$ on $C$. For a nondegenerate conic, its dimension is clearly 1. On the other hand, if $C$ is a pair of lines $l_1$, $l_2$, we have a surjection $\Omega^1_C \to \widehat{\Omega}^1_{l_1} \oplus \widehat{\Omega}^1_{l_2}$ with the kernel sheaf supported at the point of intersection of $l_1$ and $l_2$. Hence $\dim H^1(\Omega^1_C) = 2$. If $C$ is the $\tau^{-1}$-thickening of the projective line $l$, then we also have a projection $p : C \to l$. From this we get the exact sequence

$$
0 \to p^*\Omega^1_l \to \Omega^1_C \to \Omega^1_p \to 0.
$$

Now $\Omega^1_p$ is easily seen to be $i_*(\tau^{-1})$ where $i : l \to C$ is the inclusion, and hence $H^i(C, \Omega^1_p) = 0$ for all $i$. On the other hand,

$$
H^1(C, p^*\Omega^1_l) \simeq H^1(l, \Omega^1_l) \oplus H^1(l, \tau^{-1} \otimes \Omega^1_l)
$$

is of dimension 3. This proves Lemma 8.9 □
We will in fact see that if $Z \in H_{2,k}$ corresponds to a degenerate conic $C \subset P = \text{PH}^1(X, \mathcal{O})$, then $	ext{Hilb}(P(n))$ is not smooth at $Z$.

To show that $H_0$ is nonsingular at such a $Z$, we proceed as follows. Let $\tilde{Z} \subset H_2 \times U_X$ be the universal subscheme representing $H_2$. Then the map $\tilde{Z} \to H_2 \times X$ given by $(p_{H_2}, \det)$ is flat. Since the fibres are conics, it follows that this is a morphism of complete intersection \[^{[9, SGA 6, VII]}\]. Moreover, the direct image on $H_2 \times X$ of the dual of the relative dualising sheaf is locally free of rank 3. The determinant of this direct image is a line bundle and hence induces a map $\varphi : H_2 \to \text{Pic} X$. If $Z = P(E)$, is a good Hecke cycle, its image under $\varphi$ is given as follows: If $\pi : P(E) \to X$ is the projective fibration, $\varphi(Z) = \det \pi_*(T_\pi) \simeq \det \text{Ad} E$ is the trivial bundle. Hence $\varphi$ is a constant on $H_0$. On the other hand, if $Z \in Q_j$ is given by (rank 2) subbundles $F_1, F_2$ of $D_j$ containing $j^2$ with $F_1/\mathcal{R}, F_2/\mathcal{R}$ trivial, then $\omega^*_\pi \simeq \tau E \otimes (F_1 \cap F_2)|_Z$ where $E = F_1 + F_2$. Now from the exact sequence (on $P(E)$)

$$0 \to \tau^{-1}_E \otimes F_1 \cap F_2 \to \tau E \otimes F_1 \cap F_2 \to \omega^*_\pi \to 0$$

we get, on taking direct images on $X$,

$$\varphi(Z) = \det \pi_*(\tau E \otimes F_1 \cap F_2) = \det(E^* \otimes F_1 \cap F_2)$$

$$= (F_1 \cap F_2)^3 \otimes \det E^* = j^4.$$

since $F_1 \cap F_2 = j^2$ and $\det E = j^2$. Thus we have

**Lemma 8.10.** If $Z \in H_0$, then $\varphi(Z)$ is trivial, while if $Z \in Q_j$ is given by two subbundles $F_1, F_2$ of $D_j$ containing $j^2$, then $\varphi(Z) = j^4$.

Now in order to prove that $H_0$ is smooth at points $Z \in Q_k$, $k$ a node, we will show

**Lemma 8.11.** $\text{Im}(d\varphi)_Z$ has dimension $\geq 1$ (resp. $\geq 2$) if $Z$ is represented by a pair of lines (resp. a double line).

Assume the Lemma for the moment. Since $\varphi$ is a constant on $H_0$, it follows that $(d\varphi)_Z$ is zero on $T_Z(H_0)$. But by Proposition
\[ \text{dim } T_Z(H_2) \leq 3g - 2 \text{ (resp. } 3g - 1) \text{ in these cases. Now the map } (d\phi)_Z : T_Z(H_2)/T_Z(H_0) \to T\varphi(Z)(J) \text{ has image of dimension } \geq 1 \text{ (resp. } \geq 2). \text{ Hence } \text{dim } T_Z(H_0) \leq (3g - 3) \text{ in both these cases, proving } H_0 \text{ is nonsingular at these points.} \]

**Proof of Lemma 8.11** Let \( P \) be a Poincaré bundle on \( J \times X \). The sheaf \( \mathcal{F} = R^1(p_j)_*(p^2) \) on \( J \) is locally free, outside elements of order 2, of rank \( (g - 1) \). It is easily seen that \( \text{Grass}_{g-1}(\mathcal{F}) \) is isomorphic to the blow up \( \pi : \widetilde{J} \to J \) at all elements of order 2. Hence on \( \widetilde{J} \) we have a surjection \( \pi^* \mathcal{F} \to Q \to 0 \) where \( Q \) is the tautological quotient bundle or rank \( (g - 1) \). On the other hand, on \( X \times J \) we have a surjection of the vector bundle \( D \) onto \( p^*_j \mathcal{F} \). This gives rise to a surjection \( (1 \times \pi)^* D \to p^*_j Q \) on \( X \times \widetilde{J} \) where now \( Q \) is also locally free. Thus we get a family of subschemes of \( P(D) \), parametrised by \( P(Q) \). These subschemes are projective bundles associated to subbundles of \( D_j \) of rank 2 containing the kernel of \( D_j \to Q_j \) given by the surjection above. Thus \( P(Q) \times_{\widetilde{J}} P(Q) \) parametrises two families of projective line subbundles. It is easy to see that there is a flat family of schemes over \( P(Q) \times_{\widetilde{J}} P(Q) \) which is obtained as the union of these two schemes and that this family is a family of subschemes of \( U_X \) with Hilbert polynomial \( P(n) \). Thus we have a morphism \( P(Q) \times_{\widetilde{J}} P(Q) \to H_2 \). By Lemma 8.10 we have the commutative diagram

\[
\begin{array}{ccc}
P(Q) \times_{\widetilde{J}} P(Q) & \longrightarrow & H_2 \\
\downarrow & & \downarrow \\
\widetilde{J} & \longrightarrow & J \\
\downarrow & & \downarrow \\
J & \longrightarrow & J \\
\end{array}
\]

where \( 4_J \) is the map \( j \mapsto j^4 \) of \( J \). If \( Z \in H_2 \) is represented by \( X \times \) a pair of lines in \( PH^1(X, \mathcal{O}) \), then it is the image of some point in \( P(Q) \times_{\widetilde{J}} P(Q) \) over an element of order 2 of \( J \). Since the map \( \widetilde{J} \to J \) has nonzero differential at any point, and since \( P(Q) \times_{\widetilde{J}} P(Q) \)
$P(Q) \rightarrow \tilde{J}$ is a fibration, it follows that $\text{Im}(d\varphi)_Z$ has dimension $\geq 1$. If $Z$ is represented by $X \times$ a double line in $PH^1(X, \mathcal{O})$, then $Z$ can be obtained as the image of two points of $P(Q) \times_{\tilde{J}} P(Q)$ whose images $x, x'$ in $\tilde{J}$ are two different points over the given node. In fact, $x$ and $x'$ could be taken as any point on the line in $PH^1(X, \mathcal{O})$, to which $Z$ corresponds. Hence

$$\dim \text{Im}(d\varphi)_Z \geq \dim(\text{Im}(d\pi)_x + \text{Im}(d\pi)_{x'}) \geq 2.$$ 

This completes the proof of 8.11 and hence the nonsingularity of $H_0$ at $Z \in Q_k, k$ a node.

It remains to consider the case $Z \in R_k, k$ a node.

**Proposition 8.12.** Let $Z \in R_k, k$ a node. Then $\dim H^0(Z, N_{Z, U_X}) \leq 3g - 3$.

**Proof.** Let $Z = X \times l_L$, where $l$ is a projective line in $PH^1(X, \mathcal{O})$ and $L$ is a subbundle of $N = N_{X \times l, U_X}$ isomorphic to the hyperplane bundle on $l$. Then we have the exact sequence

$$0 \rightarrow L^{-1} \otimes N_{Z, U_X}|X \times l \rightarrow N_{Z, U_X} \rightarrow N_{Z, U_X}|X \times l \rightarrow 0.$$ 

Now Proposition 8.12 follows from □

**Lemma 8.13.** (i) $\dim H^0(X \times l, N_{Z, U_X}) \leq 2g - 1$.

(ii) $\dim H^0(X \times l, L^{-1} \otimes N_{Z, U_X}) \leq g - 2$.

**Proof of (i).** By § 3.4 we have the exact sequence

$$0 \rightarrow N/L \rightarrow N_{Z, U_X}|X \times l \rightarrow L^2 \rightarrow 0.$$ (8.14)

Since $H^0(X \times l, L^2) \simeq H^0(l, \tau^2)$ is of dimension 3, (i) will be proved if we show that $\dim H^0(X \times l, N/L) \leq 2(g - 2)$. Now for this computation, we need the exact sequences (Lemma 6.22 (ii))

$$0 \rightarrow \tau \otimes V/W \rightarrow N'/L \rightarrow V/W \rightarrow 0$$ (8.15)

$$0 \rightarrow N'/L \rightarrow N/L \rightarrow \tau^{-1} \otimes F \rightarrow 0$$ (8.16)
where $V = H^1(X, \mathcal{O})$, $W$ is the two dimensional subspace of $V$ corresponding to $l$, and $N'$ is the kernel of the surjection $N \to \tau^{-1} \otimes F$. From (8.15), we conclude that $H^0(X \times l, N'/L) \simeq H^0(X \times l, N/L)$, since $H^0(X \times l, \tau^{-1} \otimes F) = 0$. To compute $H^0(X \times l, N'/L)$, we note that $\dim H^0(X \times l, \tau \otimes V/W) = 2(g - 2)$ and hence i), Lemma 8.13 will be proved if we can show that the boundary homomorphism $H^0(V/W) \to H^1(\tau \otimes V/W)$ is injective. From 6.22 (ii), we have the commutative diagram

\[
\begin{array}{ccc}
V/W & \simeq & H^0(V/W) \\
& & \downarrow \\
& & H^1(\tau \otimes V/W) \simeq V \otimes V^* \otimes V/W \\
& & \downarrow \\
V & \simeq & H^0(V) \\
& & \downarrow \\
& & H^1(\tau \otimes V) \simeq V \otimes V^* \otimes V
\end{array}
\]

where the lower map is the boundary homomorphism given by the universal extension $F'$, and hence is the map $v \mapsto \text{Id}_V \otimes v$. From this it is easy to conclude that the top horizontal map is injective. This proves (i).

343 Proof of (ii). We proceed as in (i). By tensoring 8.14 with $L^{-1}$, we are reduced to computing a) $H^0(X \times l, L^{-1} \otimes N/L)$ and b) the boundary homomorphism $H^0(X \times l, L) \to H^1(X \times l, L^{-1} \otimes N/L)$. As for a), we have from 8.16 $H^0(L^{-1} \otimes N/L) \simeq H^0(L^{-1} \otimes N'/L)$ and from 8.15 $H^0(L^{-1} \otimes N'/L) \simeq H^0(V/W)$ which has dimension $g - 2$. Now (ii) will be proved if we can show that the boundary homomorphism b) is injective. To prove this, we need a description of the extension 8.14 (which is the dual of the extension 3.4 for $l_L$). In other words, for $N_{X \times P, U_X}$ we have the exact sequence 6.22 (ii)

\[0 \to \tau^{-1} \otimes T_P \to N_{X \times P, U_X} \to \tau^{-1} \otimes F \to 0.\]

Now $L = \tau^{-1} \times T_l \subset \tau^{-1} \otimes T_P | X \times l$. Any line subbundle of $N_{X \times l, U_X}$ mapping isomorphically on $L$ gives rise to a thickening $X \times l_L$. From Proposition 3.8 we get the following information about 8.14 The map $d\theta_E | X \times l$ induces a map $N_{X \times P, P(D)} =$
\[ H^1(X, \mathcal{O})_{X \times P} \rightarrow \tau^{-1} \otimes T_P. \] Let \( W \) be the inverse image of \( L = \tau^{-1} \otimes T_l \) so that we have the exact sequence (on \( X \times l \))

\[ 0 \rightarrow \tau^{-1} \rightarrow W \rightarrow \tau^{-1} \otimes T_l = L \rightarrow 0. \]

Of course, \( W \) is actually the trivial bundle with fibre \( = \) the subspace of \( P \) corresponding to \( l \). Symmetrising this, we get the sequence

\[ 0 \rightarrow \tau^{-1} \otimes W \rightarrow S^2(W) \rightarrow L^2 \rightarrow 0. \] (8.17)

Taking into account the description of the Hessian of \( \theta_E|X \times P \), we see that the push-out of (8.14) by the map \( N/L \rightarrow N_{X \times P, U_X}/\tau^{-1} \otimes T_P = \tau^{-1} \otimes F \) is isomorphic to the push-out of (8.17) by the natural map \( \tau^{-1} \otimes W \rightarrow \tau^{-1} \otimes H^1(X, \mathcal{O}) \rightarrow \tau^{-1} \otimes F \). In view of this, we have a commutative diagram

\[ \begin{array}{ccc}
H^0(X \times l, L) & \rightarrow & H^1(X \times l, L^{-1} \otimes \tau^{-1} \otimes W) H^1(X \times l, L^{-1} \otimes \tau^{-1} \otimes H^1(X, \mathcal{O})) \\
H^1(X \times l, L^{-1} \otimes N/L) & \rightarrow & H^1(X \times l, L^{-1} \otimes \tau^{-1} \otimes F)
\end{array} \]

We have to show that the left vertical map is injective. The second top horizontal map is clearly injective, while the right vertical map is even an isomorphism. Thus our assertion will be proved if the map

\[ H^0(l, L) \rightarrow H^1(l, L^{-1} \otimes \tau^{-1} \otimes W), \]

associated to (8.17) tensored with \( L^{-1} \), is injective. But this is clear since \( H^0(l, L^{-1} \otimes S^2(W)) = 0 \), thus proving Lemma 8.13 and hence Proposition 8.12.

We now have

**Theorem 8.14.** There is a natural morphism of the Hecke component \( H_0 \) into the moduli space \( U_0 \) giving a non-singular model of \( U_0 \), which is an isomorphism over the set of stable points. The reduced fibre over a non-nodal point of the Kummer variety is isomorphic to \( \mathbb{P}^{g-2} \times \mathbb{P}^{g-2} \) while that over the node is isomorphic to the union of a \( \mathbb{P}^5 \) bundle over the Grassmannian of planes in \( \mathbb{P}^{g-1} \) and a \( \mathbb{P}^{g-2} \) bundle over the Grassmannian of lines in \( \mathbb{P}^{g-1} \).
Proof. The morphism \( \pi : \text{Hilb}(H, U_0, P(m, n)) \to U_0 \) is an isomorphism over the open set \( U \) of stable points. Moreover the restriction of the morphism \( \text{Hilb}(H, U_0, P(m, n)) \to \text{Hilb}(U_X, P(n)) \) to the (schematic) closure of \( p^{-1}(U) \) is an injective (Lemma 7.6) and birational (Theorem 5.13) morphism onto \( H_0 \). Since \( H_0 \) is smooth, this morphism is an isomorphism onto \( H_0 \). This proves the first part of the theorem.

The fibre over a non-nodal point of \( \mathcal{H} \) corresponding to \( j \in J, \ j^2 \neq 1 \), is isomorphic to \( PH^1(X, j^2) \times PH^1(X, j^2) \) (Proposition 7.8). The fibre over a node is isomorphic to the union of the space of conics which are schematically contained in \( PH^1(X, \mathcal{O}) \) and the space of \( \tau^{-1} \)-thickenings of lines in \( PH^1(X, \mathcal{O}) \) which are contained in the thickening \( PH^1(X, \mathcal{O})_t \) (Proposition 7.8). The first variety is a \( \mathbf{P}^5 \)-bundle over the Grassmannian of planes in \( PH^1(X, \mathcal{O}) \) while the second is a \( \mathbf{P}^{g-2} \) bundle over the Grassmannian of lines in \( PH^1(X, \mathcal{O}) \) (See Remark 4.4 iii). ∎

Introduction. In the note [M.I.], to which this paper is a sequel, I proved the following Minkowski-type inequality, for multiplicities of primary ideals in a local noetherian Cohen-Macaulay algebra over an algebraically closed field; setting \( d = \text{dim} \mathcal{O} \), we have:

\[
es(\mathfrak{n}_1 \cdot \mathfrak{n}_2)^{1/d} \leq e(\mathfrak{n}_1)^{1/d} + e(\mathfrak{n}_2)^{1/d} \tag{*}
\]

for any two primary ideals \( \mathfrak{n}_1, \mathfrak{n}_2 \) in \( \mathcal{O} \), where \( e(\mathfrak{n}) \) denotes the multiplicity.

In this paper I will prove:

**Theorem 1.** Let \( \mathcal{O} \) be a Cohen-Macaulay normal complex analytic algebra. Then, given two ideals \( \mathfrak{n}_1, \mathfrak{n}_2 \) of \( \mathcal{O} \) which are primary for the maximal ideal, we have the equality

\[
es(\mathfrak{n}_1 \cdot \mathfrak{n}_2)^{1/d} = e(\mathfrak{n}_1)^{1/d} + e(\mathfrak{n}_2)^{1/d}
\]

if and only if there exist positive integers \( a, b \) such that

\[
\overline{\mathfrak{n}_1^a} = \overline{\mathfrak{n}_2^b}
\]

(where the bar means the integral closure of ideals, for the properties of which see [C.E.W.] and [L.T.]).

As will be clear from the proof, the conjunction of this result and (*) constitutes a generalization to arbitrary dimension of the classical result asserting the negative definiteness of the intersection matrix of the
components of the exceptional divisor of a resolution of singularities of a germ of a normal surface (see [DV], [M], [Li]).

This paper also contains two rather different applications of the above result. The first is a lightning proof of a special case of a theorem of Rees ([Re]) according to which, given two primary ideals \( n_1, n_2 \) in an equidimensional ring \( O \) such that \( n_1 \subseteq n_2 \) and \( e(n_1) = e(n_2) \), we have \( \bar{n}_1 = \bar{n}_2 \).

This result now plays a rather important role in the study of the geometry of singularities (cf. [C.E.W.] and [H.L.]) and is also used in the proof of the author’s “principle of specialization of integral dependence” (cf. [D.C.N.] App. 1) which is at the source of several results in the theory of equisingularity. The other application is a numerical characterization of those germs of real-analytic maps \( f : (\mathbb{R}^2, 0) \to (\mathbb{R}^2, 0) \) which are isotopic (in a strong sense) to a germ of a holomorphic map \( (\mathbb{C}, 0) \to (\mathbb{C}, 0) \): they are exactly those maps such that their local topological degree is equal to the square root of the degree of their complexification \( \dim_{\mathbb{R}} O_{f^{-1}(0), 0} \). This result, which is apparently new, makes use of the algebraic description of the local topological degree, given by Eisenbud and Levine in [E.L.].

Remarks. (1) The equivalence relation: \( n_1 \sim n_2 \) if and only if there exist \( a, b \in \mathbb{N} \) such that \( \bar{n}_1^a = \bar{n}_2^b \) has been studied by Samuel in [Sa], from a different viewpoint, under the name “projective equivalence”.

(2) The proof of Theorem 1 above uses only the Cohen-Macaulay property of \( O \), and the possibility of resolving singularities of 2-dimensional quotients of \( O \). Indeed it seems to be valid under some mere “excellence” assumption on \( O \), (see [Li]) and the assumption that \( O \) is Cohen-Macaulay and normal. However, I have in this redaction once again sacrificed generality to geometry, and restricted the presentation to complex analytic geometry to be able to present the ideas in their naivety. In any case, the absence of a base field would indeed make the proofs a lot more cumbersome.
1 A geometric result

The essential technical ingredient of the proof of Theorem [H] is the following result, in itself rather useful (see [T]).

Proposition. Let $O$ be a reduced Cohen-Macaulay complex analytic algebra and $n$ an ideal of $O$ primary for the maximal ideal. Set $d = \dim O$ and let as usual $n[i]$ denote an ideal $O$ generated by $i$ “sufficiently general” linear combinations of the elements of a fixed system of generators of $n$. Then we have:

(1) $\overline{n[d]} = \overline{n}$

(2) Given $f \in O$, $f \in \overline{n}$ if and only if

$$f \cdot O / n[d-1] \subset \overline{n \cdot O / n[d-1]}$$

with the necessary precision that the meaning of “sufficiently general” in the notation $n[d-1]$ occurring in (2) depends on $f$, in other words, we have (2) for a Zariski-open dense subset $U_f$ of the space of coefficients of $d - 1$ linear combinations of generators of $n$, and $U_f$ depends on $f$.

Proof. (1), which is due to Samuel [Sa2], is a consequence of Noether’s normalization theorem.

Let us prove (2): let $(W,0)$ be a representative of the germ of complex space corresponding to $O$, and such that $f$ and $n$ are the germs of a globally defined function and ideal on $W$. Let $\pi : \overline{Z} \to W$ be the normalized blowing up of $n$ in $W$. It follows from (1) and the results in ([H1] Lecture 7, [L.T]) that $\pi$ is also the normalized blowing up of an $n[d] = (f_1, \ldots, f_d) \subset n$. Let $\pi_0 : Z \to W$ be the blowing up of this $n[d]$. Since $O$ is Cohen-Macaulay, $(f_1, \ldots, f_d)$ is a regular sequence and hence (Lemma 1.9 of [H2]) we can describe $\pi_0$ as the restriction of the first projection to the subspace of $W \times \mathbb{P}^{d-1}$ defined by the ideal $(f_iT_j - f_jT_i)(1 \leq i < j \leq d)$, where $(T_1 : \ldots : T_d)$ is a system of homo-
geneous coordinates on $\mathbb{P}^{d-1}$. Let us consider the following diagram:

\[
\begin{array}{c}
\overline{Z} \\
\downarrow n \\
W \times \mathbb{P}^{d-1} \\
\downarrow \pi_0 \\
\sigma \\
\vdots
\end{array}
\]

where $n$ denotes the normalization map and $\sigma$ is the section of $G = \text{pr}_2|Z$ defined by $\sigma(\mathbb{P}^{d-1}) = \{0\} \times \mathbb{P}^{d-1}$, which is in $Z$ since $n[d] \subset m$, the maximal ideal of $O$.

Now we consider $Z \xrightarrow{\sigma} \mathbb{P}^{d-1}$ as a family of germs of curves, which like any family of curves admits a simultaneous normalization ([D,C,N]) over an open-analytic (i.e. complement of a closed analytic subset) dense subset of its parameter space hence, here, over a Zariski open dense subset $U \subset \mathbb{P}^{d-1}$. This means that for $p \in U$, the composed map $\overline{G} : \overline{Z} \to Z \to \mathbb{P}^{d-1}$ is flat in a neighbourhood of the finite set $n^{-1}(\sigma(p))$, and the multi-germ $((\overline{Z})_p, n^{-1}(\sigma(p)))$ where $(\overline{Z})_p = \overline{G}^{-1}(p)$, is the union of a finite set of germs of non-singular curves, each being the normalization of an irreducible component of the curve $(Z_p, \sigma(p))$, where $Z_p = G^{-1}(p)$. Furthermore since clearly $Z_p$ is “transversal” to $\{0\} \times \mathbb{P}^{d-1}$ which is set-theoretically the exceptional divisor of $\pi_0$, $(\overline{Z}_p, z_i)$ will be a germ of a non-singular curve transversal to the exceptional divisor $D$ of $\pi$, for $z_i \in n^{-1}(\sigma(p))$. The idea is, that these germs of curves can be used to compute multiplicities along the exceptional divisor $D$ of $\pi$. Indeed, since $n$ is a finite morphism, each irreducible component $D_i$ of $D$, which is purely of codimension 1 in $\overline{Z}$ by the hauptidealsatz, is mapped surjectively onto $\{0\} \times \mathbb{P}^{d-1}$ by $n$. Let us consider the decomposition $D = \bigcup_{i=1}^{l} D_i$ of $D$ in its irreducible components. Then by the properties of normal spaces, for each given $f \in O$ we can find a dense open analytic subset $U_i \subset D_i$ such that at each point $z \in U_i$ we have:
(1) \((D_z)_\text{red}\) is non-singular and coincides with \((D_{i,z})_\text{red}\).

(2) \(\overline{Z}\) is non-singular at \(z\).

(3) \(f \cdot O_{Z,z}\) defines a subspace having a reduced associated subspace which coincides with \((D_{i,z})_\text{red}\), in other words: the strict transform by \(\pi\) of \(f = 0\) is empty near \(z\).

By diminishing \(U\) if necessary, in a way which depends upon \(f\), since the \(U_i\) do, we can assume:

\[
D_i \cap n^{-1}(\sigma(U)) \subset U_j \quad (1 \leq i \leq l).
\]

Now for \(z \in D_i \cap n^{-1}(\sigma(U))\) we have by (1), (2), (3):

(i) \(n \cdot O_{\overline{Z},z} \cong v_1^n \cdot O_{Z,z}\), where

(ii) \(O_{\overline{Z},z} \cong \mathbb{C}\{v_1, \ldots, v_d\}\) by (2).

(iii) \(f \cdot O_{\overline{Z},z} \cong v_1^{\mu_i} \cdot O_{\overline{Z},z}\)

where \(v_i\) (resp. \(\mu_i\)) is the order with which \(n \cdot O_{\overline{Z}}\) (resp. \(f \circ \pi\)) vanishes along \(D_i\). This order being locally constant is constant on \(U_i\) since \(D_i\) is irreducible.

Setting \(p = G(n(z))\), certainly one of the components of the curve \((Z_p, \sigma(p))\) has a normalization \(((\overline{Z})_p, z)\) which goes through \(z\) and is transversal to \(D_i\) at \(z\). Therefore, since the algebra \(O_{(\overline{Z})_p,z}\) is isomorphic to \(\mathbb{C}\{t\}\), and \(v_1 \cdot O_{(\overline{Z})_p,z} = a_1 t + a_2 t^2 + \ldots\) with \(a_i \in \mathbb{C}, a_1 \neq 0\), we have, denoting by \(\nu\) the order in \(t\) of elements of \(\mathbb{C}\{t\}\), i.e. the natural valuation on \(O_{(\overline{Z})_p,z}\), that

\[
\begin{cases}
  v_i = \nu(n \cdot O_{(\overline{Z})_p,z}) & (p = G(n(z)), z \in U_i) \\
  \mu_i = \nu(f \cdot O_{(\overline{Z})_p,z}).
\end{cases}
\]

Since the polar locus of a meromorphic function in a normal space is either of codimension 1 or empty, and since by \(([H],[L,T])\) \(f \in \overline{n}\) if and only if \(f \cdot O_{\overline{Z},z} \subset n\), \(O_{\overline{Z},z}\) for all \(z \in \pi^{-1}(0)\), we see that \(f \in \overline{n}\) if and only if \(\mu_i \geq v_i ((1 \leq i \leq l))\) and this is equivalent to the fact that for
some \( p \in U \), and any irreducible component \( Z_{p,i} \) of \( Z_p = G^{-1}(p) \), we have \( f \cdot \hat{O}_{Z_{p,i} \sigma(p)} \subset n \cdot \hat{O}_{Z_{p,i} \sigma(p)} \) for all \( i \), that is: \( f \cdot O_{Z_p \sigma(p)} \subset n \cdot O_{Z_p \sigma(p)} \) (by the valuative criterion for integral dependance, see [H1], [L.T.]). But now it is clear that \( Z_p, p \in U \) is isomorphic to the curve in \((W, 0)\) defined by the \( d - 1 \) equations \( \frac{f_1}{t_1} = \ldots = \frac{f_d}{t_d} \) where \((t_1 : \ldots : t_d)\) are the coordinates of \( p \), i.e. the equations \( f_i t_{i+1} - f_{i+1} t_i = 0 (1 \leq i \leq d - 1) \), and this means that \((Z_p, \sigma(p))\) is the curve defined by a \( n^{[d]} \) according to our conventions. This ends the proof of Proposition 1. □

**Note.** The following diagram may perhaps help the reader.

![Diagram](image-url)
Remark. There is not necessarily a bijection between the irreducible components of $Z_p$, $p \in U$ and those of $D$. What counts is that each $(\mu_i, v_i)$ appears at least once as the valuation of $(n, f)$ given by an irreducible component of $Z_p$ and that all these valuations occur in this way. This fact is important in the construction of invariants; see ([T], proof of Theorem 2).

2 Proof of Theorem 1

The assertion is obvious when $d = 0, 1$ since $O$ is then $\mathbb{C}, \mathbb{C}\{t\}$. We therefore assume $d \geq 2$. Let us recall from [M.I.] that given two primary ideals $n_1$ and $n_2$ of $O$, we set

$$e_i = e\left(n_1^{[i]} + n_2^{[d-i]}\right)$$

and showed that (*) was a consequence of inequalities

$$e_i^d \leq e_0^d \cdot e_{d-1}^d \quad (1 \leq i \leq d)$$

themselves consequences of:

$$\frac{e_i}{e_{i-1}} \geq \frac{e_{i-1}}{e_{i-2}} \quad (2 \leq i \leq d)$$

All this in view of the equality

$$e(n_1 \cdot n_2) = \sum_{i=0}^{d} \binom{d}{i} e_i$$

of ([C.E.W., Chap. I § 2]).

The idea being that by induction on $d$ it is enough to prove

$$\frac{e_d}{e_{d-1}} \geq \frac{e_{d-1}}{e_{d-2}}$$

and that this is in fact a result on surfaces: setting $O = O/n_1^{[d-2]}$, $\tilde{n}_i = n \cdot \tilde{O}$, $i = 1, 2$ we saw, thanks to the Cohen-Macaulay property of $O$, that
Let $a/b$ denote the common value of these ratios. It follows easily from the results in (C.E.W. Chap. I §2) that if we replace $n_1$ by $n_1^a$ and $n_2$ by $n_2^b$, $e_i$ is replaced by $a^i b^{d-i} e_i$. After this substitution we see that the proof of Theorem 1 is reduced to proving that if $e_d = e_{d-1} = \cdots = e_1 = e_0$, then $\bar{n}_1 = \bar{n}_2$. Now by the theorem of Bertini for normality (see [F]) we have that $O/n_1^{[d-2]}$ is a normal analytic algebra if $O$ is so, and then by the classical result ([DV], [Li], [M]) the matrix of the $\langle E_k, E_{k'} \rangle$ is negative definite, from which follows immediately in view of (1) that if $\bar{e}_2 = \bar{e}_1 = \bar{e}_0$ we have $u_k = v_k$ for all $k$, hence $\bar{n}_1 \cdot O_S = \bar{n}_2 \cdot O_S$ (since $\bar{n}_1 \cdot O_S$ and $\bar{n}_2 \cdot O_S$ are invertible on $S$) and from this follows $\bar{n}_1 = \bar{n}_2$ in $O/n_1^{[d-2]}$. Let us now show that $n_1 \subset \bar{n}_2$ in $O$: given $f \in n_1$, to show that $f \in \bar{n}_2$, it is sufficient, in view of Proposition 1, to show that $f \cdot O/n_1^{[d-1]} \subset n_2 \cdot O/n_1^{[d-1]}$, but
certainly a $\mathcal{O}/\mathfrak{n}_1^{[d-1]}$ is a quotient of a $\mathcal{O}/\mathfrak{n}_1^{[d-2]}$ as above, and since $\bar{\mathfrak{n}}_1 = \bar{\mathfrak{n}}_2$ we have

$$f \cdot \mathcal{O}/\mathfrak{n}_1^{[d-2]} \subset \bar{\mathfrak{n}}_2 \cdot \mathcal{O}/\mathfrak{n}_1^{[d-2]}$$

hence a fortiori

$$f \cdot \mathcal{O}/\mathfrak{n}_1^{[d-1]} \subset \bar{\mathfrak{n}}_2 \cdot \mathcal{O}/\mathfrak{n}_1^{[d-1]}.$$ 

This shows that for any $f \in \mathfrak{n}_1$, $f \in \bar{\mathfrak{n}}_2$, i.e., $\mathfrak{n}_1 \subset \bar{\mathfrak{n}}_2$ whence $\bar{\mathfrak{n}}_1 = \bar{\mathfrak{n}}_2$ by symmetry. This proves that if $e(\mathfrak{n}_1 \cdot \mathfrak{n}_2)^{1/d} = e(\mathfrak{n}_1)^{1/d} + e(\mathfrak{n}_2)^{1/d}$ we have $\bar{\mathfrak{n}}_1^a = \bar{\mathfrak{n}}_2^b$. The converse is an immediate consequence of the fact that $e(\bar{\mathfrak{n}}) = e(\mathfrak{n})$ ([C.E.W.] Chap. 0) and the remark made about the behaviour of the $e_i$ under the operation $\mathfrak{n} \rightarrow \mathfrak{n}^d$. This ends the proof of Theorem [I].

**Remark.** We have seen in the course of the proof that, thanks to (1), when $d = 2$, Theorem [I] and (*) together follow from the negative definiteness of $\langle E_k, E_k' \rangle$.

### 3 Applications

#### 3.1 First application: the Theorem of Rees (in a special case).

**Theorem (Rees).** Let $\mathcal{O}$ be a Cohen-Macaulay normal analytic algebra, $\mathfrak{n}_1$ and $\mathfrak{n}_2$ two ideals of $\mathcal{O}$ primary for the maximal ideal and such that $\bar{\mathfrak{n}}_1 \subseteq \bar{\mathfrak{n}}_2$ and $e(\mathfrak{n}_1) = e(\mathfrak{n}_2)$. Then we have $\bar{\mathfrak{n}}_1 = \bar{\mathfrak{n}}_2$.

**Proof.** It is easy to see that for any positive integer $a$, we have $\bar{\mathfrak{n}}_1 = \bar{\mathfrak{n}}_2 \iff \bar{\mathfrak{n}}_1^a = \bar{\mathfrak{n}}_2^a$ (e.g., use the valuative criterion for integral dependence, [H], [L.T.]). Now let us set $e(\mathfrak{n}_1) = e(\mathfrak{n}_2) = e$. Since for any two primary ideals, $\mathfrak{n} \subseteq \mathfrak{n}'$ implies $e(\mathfrak{n}) \geq e(\mathfrak{n}')$, $\mathfrak{n}_1 \subseteq \mathfrak{n}_2$ implies $e(\mathfrak{n}_1 \cdot \mathfrak{n}_2) \geq e(\mathfrak{n}_2^2) = 2^d e$. Using (*) now we see that

$$2 \cdot e^{1/d} \leq e(\mathfrak{n}_1 \cdot \mathfrak{n}_2)^{1/d} \leq e^{1/d} + e^{1/d} = 2 \cdot e^{1/d},$$

hence we have equality, and by Theorem [I] there exist $a, b \in \mathbb{N}$ such that $\bar{\mathfrak{n}}_1^a = \bar{\mathfrak{n}}_2^b$. But we saw that $e(\mathfrak{n}^d) = a^d e(\mathfrak{n})$ and $e(\bar{\mathfrak{n}}) = e(\mathfrak{n})$. Since $e(\mathfrak{n}_1) = e(\mathfrak{n}_2)$, the above equality therefore implies $a = b$, from which the theorem follows. □
3.2 Second Application  Let \( f : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^n, 0) \) be a germ of a real analytic mapping, described by \( f_1, \ldots, f_n \) in \( \mathbb{R}\{x\} = \mathbb{R}\{x_1, \ldots, x_n\} \) and such that \( Q(f) = O_{f^{-1}(0),0} = \mathbb{R}\{x\}/(f_1, \ldots, f_n) \) is a finite dimensional vector space over \( \mathbb{R} \). Set \( q = \dim_{\mathbb{R}} Q(f); q \) is also the topological degree of the complexified map \( f^{\mathbb{C}} : (\mathbb{C}^n, 0) \rightarrow (\mathbb{C}^n, 0) \). It was proved in \([E.L.]\) that the topological degree \( \deg f \) of \( f \) satisfies
\[
|\deg f| \leq q^{1-1/n}
\]
and this inequality was proved as follows: first one proved that \( |\deg f| \leq e(\pi n^{n-1} + m^{[1]}) \) where \( \pi \) is the ideal generated by \( (f_1, \ldots, f_n) \) in \( \mathbb{C}\{x\} \) and \( m \) is the maximal ideal, then one used the inequality \([1.2]\) from \([M.I.]\) quoted above to show that
\[
e(\pi n^{n-1} + m^{[1]}) \leq e(n^{1-1/n}) = q^{1-1/n}.
\]

Let us consider the special case \( n = 2 \). We have \( |\deg f| \leq q^{1/2} \) and there is at least one case where we have equality: let \( f \) be a holomorphic map \( (\mathbb{C}, 0) \rightarrow (\mathbb{C}, 0) \) given by \( z \mapsto z^k \). Setting \( z = x_1 + ix_2 \) we see that the components of \( f \), \( f_1(x_1, x_2) \) and \( f_2(x_1, x_2) \) are homogeneous polynomials of degree \( k \). From the additivity of intersection multiplicities follows that in this case \( q = k^2 \). By writing \( z = \rho e^{i\theta} \) we see that all the zeroes of \( f_1 \) and \( f_2 \) are real, and the \( k \) lines in \( \mathbb{R}^2 \) where \( f_1 \) vanishes alternate with the \( k \) lines where \( f_2 \) vanishes, being obtained from them by a rotation of \( \pi/2k \). Furthermore each of the sets of lines divides \( \mathbb{R}^2 \) in \( 2k \) sectors. One readily checks that \( \text{Re} z^k = t, \text{Im} z^k = 0 \) is a regular fibre of \( f \), at each point of which \( f \) preserves the orientation, and which contains \( k \) points, since \( \text{Re} z^k = t \) defines a curve in every second sector among those defined by \( \text{Re} z^k = 0 \), which is asymptotic to the walls of this sector and meets the lines \( \text{Im} z^k = 0 \) transversally. We remark that the fact that \( f \) is orientation preserving comes from the following property of \( f_2 = \text{Im} z^k, f_1 = \text{Re} z^k \):

(OR) In each sector where \( f_1 > 0 \), the sign of \( f_2 \) changes from \(-\) to \( +\) as we cross the line \( f_2 = 0 \) circulating in the trigonometric direction (counterclockwise).
Having seen this, we have no difficulty in proving

**Lemma 1.** Let \( f : (\mathbb{R}^2, 0) \to (\mathbb{R}^2, 0) \) be given by two homogeneous polynomials \( f_1, f_2 \) of the same degree \( k \). Then we have \( \deg f = k \) if, and only if, \( f_1 \) and \( f_2 \) both have all their roots real, these roots alternate and the condition (OR) is satisfied.

Indeed, if they do not both have all their roots real, we can find a regular fibre with less than \( k \) points, hence \( |\deg f| < k \). If they do not alternate, then we can find two points in a fibre with \( k \) points, where the orientation is not the same, hence again \( |\deg f| < k \) and finally if the first two conditions are satisfied we have \( \deg f = \pm k \), and condition (OR) implies \( \deg f - k \) (and conversely). We now prove:

**Lemma 2.** Let \( f = (f_1, f_2) \) and \( f' = (f_1', f_2') \) be two mapping satisfying the condition of Lemma 1. Then there is a 1-parameter family \( (f_t)_{t \in [0, 1]} \) of mappings, all satisfying the condition of Lemma 1 such that \( f_0 \approx f \) and \( f_1 \approx f' \).

**Proof.** After a suitable choice of coordinates, we can write (up to the isomorphism corresponding to a constant factor)

\[
f_1 = \prod_{i=1}^{k} (x_1 - \alpha_i x_2) \quad f_2 = \prod_{i=1}^{k} (x_1 - \beta_i x_2) \quad \alpha_i, \beta_i \in \mathbb{R}
\]

with \( \alpha_1 < \beta_1 < \alpha_2 < \ldots < \alpha_k < \beta_k \), and similarly

\[
f_1' = \prod_{s=1}^{k} (x_1 - \alpha'_s x_2), \quad f_2' = \prod_{i=1}^{k} (x_1 - \beta'_i x_2)
\]

with \( \alpha'_1 < \beta'_1 < \alpha'_2 < \ldots < \alpha'_k < \beta'_k \).

Then the family given by

\[
f_{t,1} = \prod_{i=1}^{k} (x_1 - (t\alpha'_i + (1-t)\alpha_i) x_2)
\]

\[
f_{t,2} = \prod_{i=1}^{k} (x_1 - (t\beta'_i + (1-t)\beta_i) x_2)
\]

for \( 0 \leq t \leq 1 \), obviously gives the answer. \( \square \)
Theorem 2. Let \( f : (\mathbb{R}^2, 0) \to (\mathbb{R}^2, 0) \) be a germ of a real-analytic mapping with algebraic degree \( q(q = \dim_{\mathbb{R}} O_{f^{-1}(0), 0}) \). Then \( f \) can be continuously deformed, with degree and algebraic degree both constant, to a holomorphic mapping \((\mathbb{C}, 0) \to (\mathbb{C}, 0)\) if and only if \( \deg f = q^{1/2} \).

Proof. The condition is obviously necessary, after what we have just seen. Let us prove it sufficient. From what we saw above, the equality \( \deg f = q^{1/2} \) implies \( e(n^1[1] + m^1[1]) = e(n)^{1/2} \) which, since \( e(m) = 1 \), and in view of the equality \((E. \ 1)\) quoted in \( \S 2 \) gives \( e(n \cdot m)^{1/2} = e(n)^{1/2} + e(m)^{1/2} \). From Theorem 1 we deduce the existence of integers \( a, b \) such that \( n^a = m^b \) and from the properties of multiplicities we deduce that in fact we must have \( n = m^k \) in \( C\{x_1, x_2\} \), where \( k = q^{1/2} = \deg f \).

We are going to show that this implies that the components \( f_1, f_2 \) of \( f \) can be taken (up to isotopy) to be homogeneous polynomials of degree \( k \). Let \( n' \) be the ideal in \( C\{x_1, x_2\} \) generated by those among \( (f_1, f_2) \) which are in \( m^k - m^{k+1} \); we have \( n' \subset n \subset n' + m^{k+1} \) hence, since \( \bar{n} = m^k \), we have \( n' + m \cdot m^k = m^k \) which by the integral Nakayama Lemma ([C.E.W.] Chap. 11, 2.4) implies \( \bar{n}' = m^k \), which in turn implies that \( n' \) is generated by at least two elements, whence \( n' = n \). Now we know \( f_i \in m^k - m^{k+1}, i = 1, 2 \). We can set

\[
\begin{align*}
f_1 &= P_k + P_{k+1} + \ldots \\
f_2 &= Q_k + Q_{k+1} + \ldots
\end{align*}
\]

where \( P_i \) (or \( Q_i \)) is an homogeneous polynomial of degree \( i \) in \( x_1 \) and \( x_2 \).

We know furthermore that since \( n' = (P_k, Q_k) \) has at its integral closure \( m^k \), \( \dim_{\mathbb{R}} R\{x_1, x_2\}/(P_k, Q_k) = \dim_{\mathbb{R}} R\{x_1, x_2\}/(f_1, f_2) = q \). Consider the family of functions

\[
\begin{align*}
f_{1,t} &= P_k + tP_{k+1} + \ldots + t^lP_{k+l} + \ldots \\
f_{2,t} &= Q_k + tQ_{k+1} + \ldots + t^lQ_{k+l} + \ldots
\end{align*}
\]

the family of ideals \( \mathcal{F}_t = (f_{1,t}, f_{2,t}) \cdot R\{x_1, x_2\} \) and the family of algebras \( Q_t = R\{x_1, x_2\}/\mathcal{F}_t \). For any \( t \neq 0 \), \( Q_t \) is isomorphic to \( Q(f) \) as an \( R \)-algebra (change \( x_i \) to \( tx_i \) in \( f \), and divide by \( t^k \)), and \( Q_0 = R\{x_1, x_2\}/(P_k, Q_k) \).
We now use the main result of \cite{[E.L.]}: all the \(Q_t\) are isomorphic as vector spaces; choosing a linear form \(l : Q_0 \to \mathbb{R}\) such that \(l(J_0) > 0\), where \(J_0\) is the Jacobian determinant of \((P_k, Q_k)\), we can extend \(l\) to \(Q_t\) and denoting by \(J_t\) the Jacobian determinant of \((f_{1,t}, f_{2,t})\), we get \(l(J_t) > 0\) for \(t\) sufficiently small. According to Theorem 1.2 of \cite{[E.L.]}, we have:

1. the bilinear form on \(Q_t\) defined by \(\langle p, q \rangle = l(p \cdot q)\) is non-singular for all sufficiently small \(t\), therefore its signature is independent of \(t\) near \(t = 0\).

2. This signature is equal to \(\deg f\) for \(t \neq 0\) and to the degree of the map \(f_0 : (\mathbb{R}^2, 0) \to (\mathbb{R}^2, 0)\) defined by \((P_k, Q_k)\) for \(t = 0\).

Hence \(\deg f_0 = k = q^{1/2}\) and Theorem 2 now follows easily from Lemmas 1 and 2.

\[\square\]

Remarks.

1. The key point is to check that the assumption \(\deg f = q^{1/2}\) implies that the tangent cones at 0 of \(f_1 = 0\) and \(f_2 = 0\) have the same degree, and no common component. This is what Theorem 1 does for us in the above proof.

2. Theorem 2 above is valid also for \(C^\infty\) maps \(f : (\mathbb{R}^2, 0) \to (\mathbb{R}^2, 0)\) such that \(\text{dim} \mathcal{E}_2/(f_1, f_2) < \infty\) where \(\mathcal{E}_2\) is the ring of germs of \(C^\infty\) function on \((\mathbb{R}^2, 0)\), since the finiteness assumption implies that in those problems we have finite determinacy (see \cite{[E.L.]}).

3. It is an interesting problem to find invariants of algebras of the form \(\mathbb{R}\{x_1, \ldots, x_n\}/(f_1, \ldots, f_n)\) of finite dimension over \(\mathbb{R}\) which allow one to determine when two such algebras (or the corresponding germs of mappings \((\mathbb{R}^n, 0) \to (\mathbb{R}^n, 0)\)) can be continuously deformed into one another with constant dimension of the algebras (i.e. algebraic degree) and degree.
